

## ServoPac TT User Guide

**Digital drive  
for sinusoidal  
synchronous  
AC motors**

## WARNING

This is a general manual describing a series of servo drives having output capability suitable for driving AC brushless sinusoidal servo motors.

Please see also:

- **ServoPac TT Installation Guide** for the hardware installation of the drive (mounting, wiring, ...).
- **ServoPac TT STO** for the Safe Torque Off function
- **ServoPac TT Templates** for the templates of target applications.
- **Gem Drive Studio software Quick Start** manual for the drive parameterization.
- **EtherCAT® fieldbus interface** manual for the TT-ETH version.
- **ServoPac GDPS** manual, for the use of the GDPS power supply unit.

**Instructions for storage, use after storage, commissioning as well as all technical details require the MANDATORY reading of the manual before getting the drives operational.**

**Maintenance procedures should be attempted only by highly skilled technicians having good knowledge of electronics and servo systems with variable speed (EN 60204-1 standard) and using proper test equipment.**

The conformity with the standards and the "CE" approval is only valid if the items are installed according to the recommendations of the drive manuals. Connections are the user's responsibility if recommendations and drawings requirements are not met.

### CAUTION

Any contact with electrical parts, even after power down, may involve physical damage.  
Wait for at least 10 minutes after power down before handling the drives (a residual voltage of several hundreds of volts may remain during a few minutes).

### ESD INFORMATION (ElectroStatic Discharge)

TRANSTECHNIK drives are conceived to be best protected against electrostatic discharges. However, some components are particularly sensitive and may be damaged if the drives are not properly stored and handled.

#### STORAGE

- The drives must be stored in their original packing.
- When taken out of their packing, they must be stored positioned on one of their flat metal surfaces and on a dissipating or electrostatically neutral support.
- Avoid any contact between the drive connectors and material with electrostatic potential (plastic film, polyester, carpet ...).

#### HANDLING

- If no protection equipment is available (dissipating shoes or bracelets), the drives must be handled via their metal housing.
- Never get in contact with the connectors.

#### ELIMINATION

In order to comply with the 2002/96/EC directive of the European Parliament and of the Council of 27 January 2003 on waste electrical and electronic equipment (WEEE), all TRANSTECHNIK devices have got a sticker symbolizing a crossed-out wheeled dustbin as shown in Appendix IV of the 2002/96/EC Directive.

This symbol indicates that TRANSTECHNIK devices must be eliminated by selective disposal and not with standard waste.

TRANSTECHNIK does not assume any responsibility for any physical or material damage due to improper handling or wrong descriptions of the ordered items.

Any intervention on the items, which is not specified in the manual, will immediately cancel the warranty.

TRANSTECHNIK reserves the right to change any information contained in this manual without notice.

| <b>3.3 - OBJECT LIST .....</b>                      | <b>228</b> |

# Chapter 1 - General Description

## 1.1 - INTRODUCTION

**ServoPac TT** all-digital drives with sinusoidal PWM control are servo drives that provide the control of brushless AC motors with position sensor.

The standard control interface can be:

- CANopen,
- EtherCAT®<sup>1</sup>,
- analog,
- stepper motor emulation,
- logic I/Os.

But the **ServoPac TT** range also offers more sophisticated functions such as:

- DS402 including position capture,
- Master/slave and electronic gearing,
- Positioner with motion sequencing.

All versions are delivered as standard with the integrated protection function **Safe Torque Off: STO SIL 2**.

With its very small dimensions, the **ServoPac TT** drive is available in various designs:

- stand-alone or multi-axis,
- wall mounting (standard), push-through or cold plate cooling.

Series **ServoPac TT** drives are fully configurable in order to fit various applications. Both drive versions of the ServoPac TT range are described below.

The **ServoPac TT** version with CANopen interface can be used in the following application types:

- Axes controlled by CANopen fieldbus according to the DS402 protocol,
- Stand-alone operation as a motion sequencer with control by means of logic I/Os,
- Traditional analog speed amplifier with +/- 10 V command and position output by A, B, Z encoder signal emulation,
- Stepper motor emulation with PULSE and DIR command signals.

The **ServoPac TT** version with EtherCAT® interface can be used in the following application types:

- Axes controlled by EtherCAT® fieldbus according to the DS402 protocol,
- Stand-alone operation as a motion sequencer with control by means of logic I/Os.

The configuration and parameterization software tool Gem Drive Studio allows a quick configuration of the **ServoPac TT** drives according to the application requirements.

In this manual, we will use the generic and standard vocabulary to describe these variables. The variables are specified as “parameters” from the communication side.

Each parameter is identified by:

- an Index number and a Sub-index number,
- a Name.

---

<sup>1</sup> EtherCAT® is a registered trade mark and a patented technology of Company Beckhoff Automation GmbH, Germany.

Each parameter has the following properties:

- Access type: it is possible to read it, to write it....; "ro" means "read only", "rw" means "read & write".
- Length: byte, word (16 bit), long (32 bit).
- Possibility or not to access the parameter by using fast communication CANopen services (Process Data Object service PDO). If yes, the field "PDO mapping" of the object dictionary will be "yes".

Convention: A numerical field can be filled-in with numerical values described as "hexadecimal" or "decimal". An hexadecimal value will be written "0xvalue".

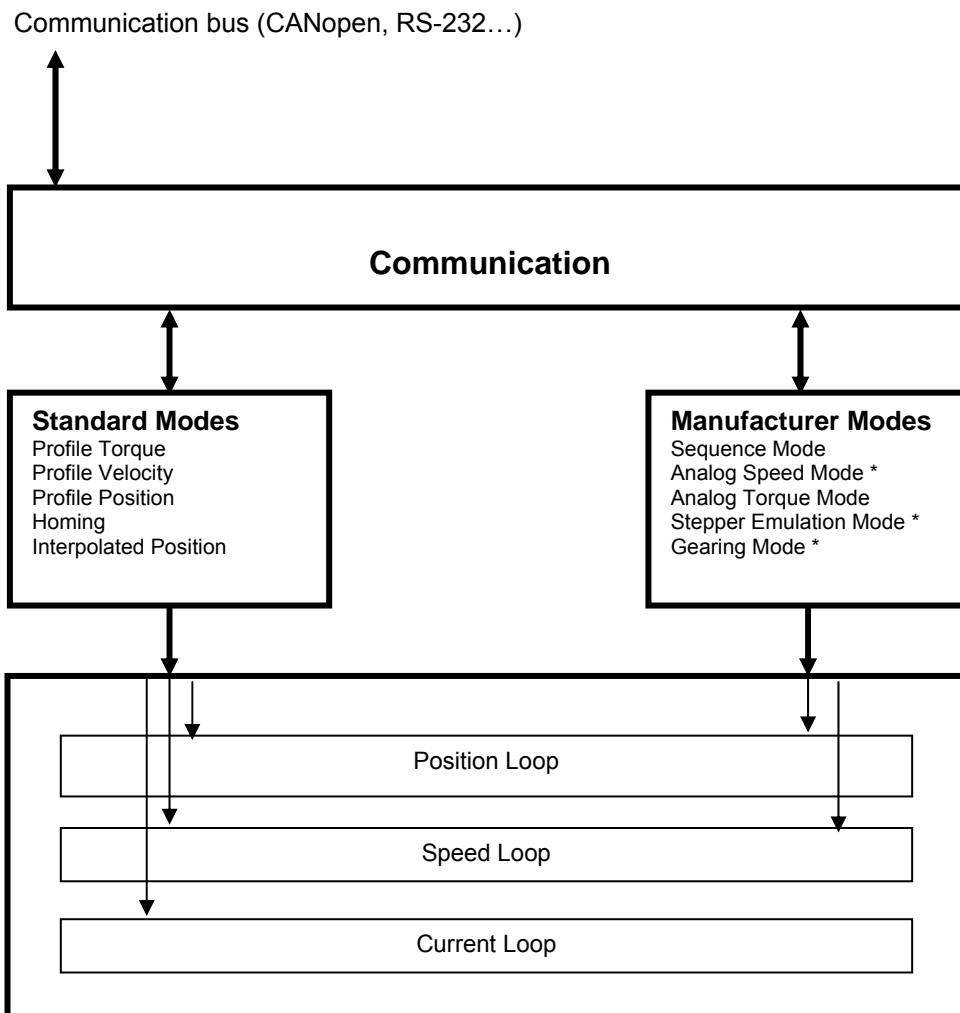

## 1.2 - ARCHITECTURE

**ServoPac TT** is a freely configurable drive.

The drive configuration includes servo-loop parameters, motor and sensor parameters, communication parameters and I/O configuration parameters. The configuration parameters can be stored into the drive non-volatile memory.

The **ServoPac TT** drive can be controlled via the fieldbus (CANopen or EtherCAT®), via the analog input (analog speed drive), via the PULSE and DIR inputs (stepper emulation) or via the digital I/Os (stand-alone positioner) according to the selected operation mode.

The following diagram describes the functional architecture of the **ServoPac TT** drive:

\* Note: Analog Speed Mode, Stepper Emulation Mode and Gearing Mode are not available in the EtherCAT® version.

### **1.3 - OTHER DOCUMENTS**

- ServoPac TT Installation guide.
- ServoPac TT "Safe Torque Off" specification.
- ServoPac TT Templates.
- Gem Drive Studio Quick Start guide
- EtherCAT® fieldbus interface.
- ServoPac GDPS manual, for the use of the ServoPac GDPS power supply unit

## Chapter 2 - Commissioning

This chapter describes the commissioning procedure of the drive by means of the "Gem Drive Studio" software.

### 2.1 - PC SOFTWARE INSTALLATION

The **Gem Drive Studio** software is PC compliant under Windows® and allows an easy parameterization of the ServoPac TT drive.

#### Minimum Configuration

The use of the **Gem Drive Studio** software requires the minimum PC configuration described below:

- Pentium III processor,
- 512 MB RAM,
- 15" screen, 256 colour screen, 1024x768 resolution
- Keyboard + mouse
- Windows® XP Service pack2 operating system
- Microsoft .NET Framework V3.5 installed
- 55 MB available on hard disk
- RS232 cable or USB/RS232 adapter cable.

Important note: If using a USB/RS232 adapter, it is highly recommended to choose an industrial product rather than a consumer product, because of reliability and performances. It is in particular mandatory to have shielded cables (see application note regarding the use of USB/RS232 adapters).

#### Restrictions

Under Windows 7 Professional 64 bit, the Service Pac 1 must be installed.

#### Installation

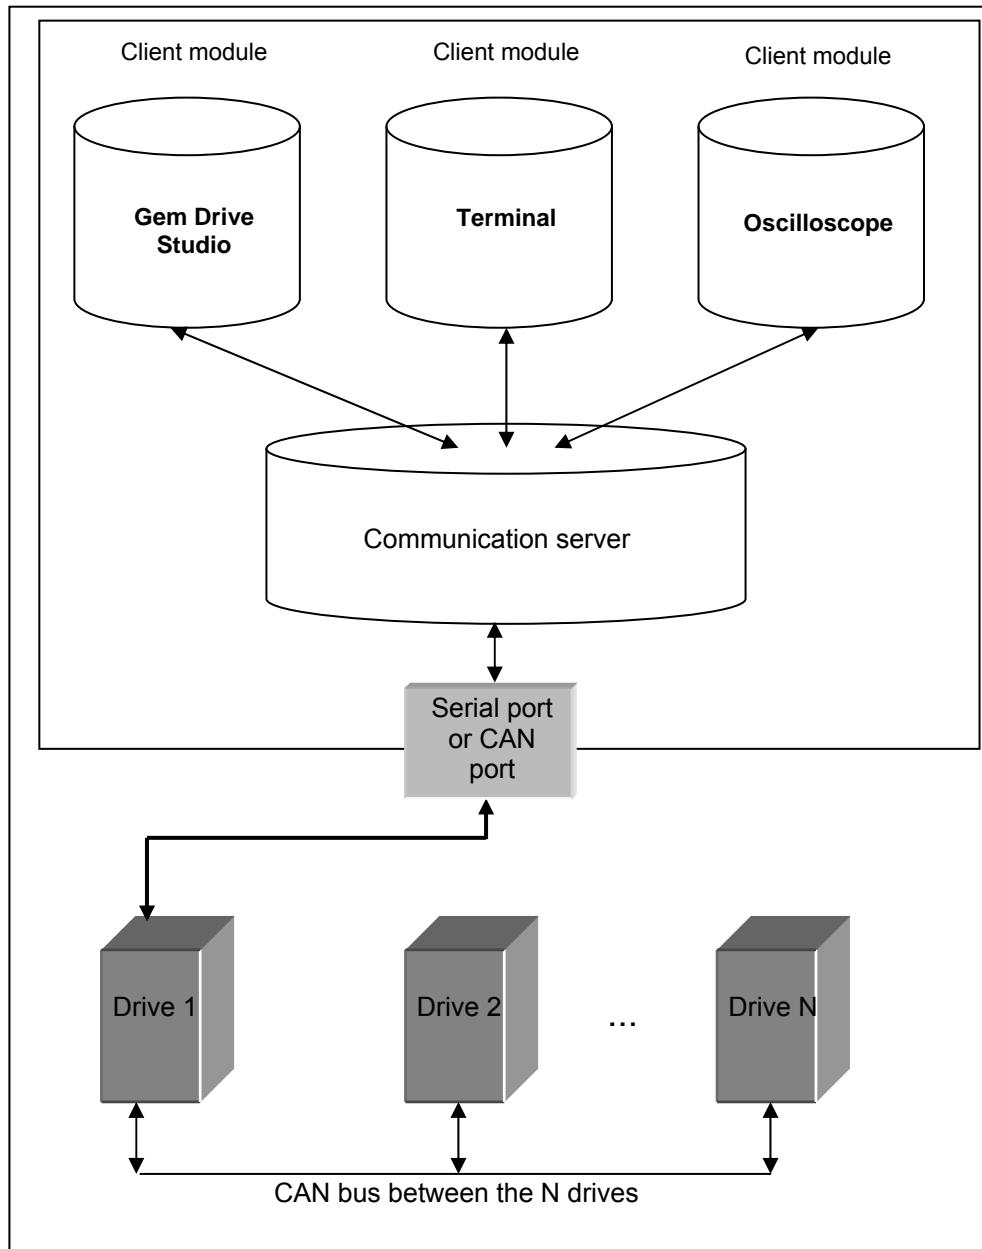

During the installation, one or several messages indicating that a currently copied file is older than a file already existing on the PC, may be displayed. In this case, keep the PC file.

When installing the software, 3 icons are created on the desktop:

- "GemDriveStudio", for launching the main interface.
- "GemDriveOscillo", for launching the digital oscilloscope.
- "GemDriveTerminal", for opening a dialog terminal.

## Architecture of the software

The software is made of several independent software modules. Each of them can communicate with the drive(s) via a communication server.

- The server is automatically started when a client module is trying to establish a communication with a drive.
- The server is commissioning the drivers of the hardware peripherals.
- The server stops when the last connected client is stopped.
- The format of the exchanged data is the same whichever the communication type (RS232, CAN, ...).

## 2.2 - STARTING THE SOFTWARE

### User levels

When starting the software, various user levels can be selected. The drive parameter modification levels are protected by passwords. **Administrator** is the highest level with full access.

### Passwords

The Administrator can change all passwords by using the Tools/User identification menu. The default **password** for the administrator level is "admin".

### Project management

The Gem Drive Studio software allows the parameterization of all **ServoPac TT** drives for a given application. All **ServoPac TT** drives of a given application, connected together via CANopen, are included in the same **project**. Each **ServoPac TT** drive of the project is identified by a **node ID** which is coded on the drive front panel by means of micro-switches. The **ServoPac TT** drive node ID code values must all be different from each other in the same project.

The different software commands allow:

- Creating a project,
- Opening an existing project,
- Adding and/or removing axes in the project,
- Archiving/Unarchiving a project,

### Axis directory

For each new axis of the project, the software creates, in the project file directory, a new directory with the axis name. There will then be one directory per axis and each of these directories will contain the parameter files and the sequence files.

### Object dictionary

Each parameter (object) of the drive can be defined by an **Index**, a **Sub-index** and several properties (Save type, Data type, Unit, Min value, Max value, Default value). The drive supported object list with the corresponding properties is the **object dictionary** file in XML format. This file, named **EEDS** (for Extended Electronic Data Sheet), is used by Gem Drive Studio to read and write parameters on the drive. A Gem Drive Studio software command allows the import of an EEDS file to the EEDS library.

### Starting Gem Drive Studio

- Start the software with the **Administrator** level.
- Create the **project**:
  - Define a project name
  - Select an output directory
  - Define all the axes of the application.
- Define the different project **axes**:
  - Select the device type
  - Define the axis name
  - Identify the Node ID for this axis

Once a project created, each axis can be independently selected by using the tree structure.

## 2.3 - DRIVE COMMUNICATION

### Powering the drives

Please see manual "Installation Guide" before switching on the drives for the first time. For switching on the drives, proceed as follows:

- Switch on the +24 V auxiliary supply:

The red front panel LED "**ERR**" must be blinking ("Undervolt" error displayed).  
The AOK relay contact is closed. It is then possible to control the Power ON relay.

- Switch on the power supply:

The red **ERR** LED must be unlit. The drive is ready to be enabled.

### Starting the communication

The **Gem Drive Studio** software can communicate with the drives by using either the RS232 serial link or the CANopen fieldbus. All drives of the application are connected together via CANopen:

- Set the node ID code value by using the micro-switches on the front panel for all drives of the application (code values must be different from each other),
- Connect the serial link RS232 or the CANopen fieldbus between the PC and one drive of the application,
- Start the **Gem Drive Studio** software on the PC,
- Open the **Project**,
- Select the communication interface between the drives and the PC (Serial link or CANopen bus),
- Start the communication,
- If the **Project** is not defined, use the **Scan** function for starting the communication.

## 2.4 - PARAMETER SETTING

This chapter describes the parameterization procedure of the drive by means of the "Gem Drive Studio" software.

### 2.4.1 - CONFIGURATION OF THE DRIVE

For a standard drive application (analog speed drive, stand-alone positioner or stepper emulation), select the required target application in the **Device Config** window. In this case, the drive input and output functionalities as well as the drive operation mode are automatically set according to the selected application template. The **GemDriveStudio** parameterization windows are also adapted to the target application in order to display only the required parameters and functions.

In order to access the full parameter set and operation modes, select **Expert** mode in the **Device Config** window.

### 2.4.2 - CONFIGURATION OF THE MOTOR

If the motor is referenced in the **Gem Drive Studio** motor catalog, it can be simply selected in the proposed motor list.

If the motor is not referenced in the **Gem Drive Studio** motor catalog, the motor parameters can be manually adjusted or calculated by using the drive's built-in procedures: current loop calculation, auto-phasing. The motor can then be referenced in the **Gem Drive Studio** motor catalog by using the **Add new motor** command (see **Gem Drive Studio** quick start manual). The motor and the position sensor parameter values are manually entered and then saved in the **Gem Drive Studio** motor catalog with a new motor reference.

### 2.4.2.1 - Selection in the motor list

In the motor list, select the motor used in the application. The motor selection will automatically set the following drive parameters: position sensor (resolver or encoder), thermal sensor, current limits, speed limit, current loop gains and motor control parameters.

Check that the thermal sensor calibration is complying with the motor application and modify the threshold values if necessary.

Check that the current limit and the  $I^2t$  protection adjustment are complying with the motor application, and modify them if necessary.

Check that the motor speed limit is complying with the application and reduce its value if necessary.

If external inductances are serially connected with the motor winding for filtering, renew the current loop gain calculation by using the total value of the phase-to-phase inductance.

If the position sensor adjustment (resolver or absolute encoder) has been modified, the auto-phasing procedure can be used to find the new adjustment (position offset).

### 2.4.2.2 - Manual motor configuration

If the motor configuration must be manually made (motor is not referenced in the **Gem Drive Studio** catalog), adjust first the motor position sensor parameters (resolver or encoder) before the motor parameters.

#### **Configuration of the motor thermal sensor**

##### **Selection of the sensor type**

The motor can be equipped either with a CTN sensor (ohmic resistance = decreasing temperature function) or with a CTP sensor (ohmic resistance = increasing temperature function).

Check that the selected thermal sensor type actually corresponds to the sensor type mounted on the application motor.

##### **Triggering threshold adjustment**

Enter the sensor ohmic value (kOhm) corresponding to the required temperature value for the release of the motor over-temperature protection, according to the manufacturer's specifications.

##### **Warning threshold adjustment**

Enter the sensor ohmic value (kOhm) corresponding to a warning temperature value. When the warning temperature is reached, the warning bit in status word is set.

##### Note

When using a CTN sensor, the warning ohmic value will be higher than or equal to the triggering ohmic value. When using a CTP sensor, the warning ohmic value will be lower than or equal to the triggering ohmic value.

#### **Current limit adjustment**

The **Maximum current** parameter defines the maximum output current value of the drive. It may vary between 20 % and 100 % of the drive current rating.

The **Rated current** parameter defines the limitation threshold of the drive output RMS current ( $I^2t$ ). It can vary between 20 % and 50 % of the drive current rating.

#### **$I^2t$ protection adjustment**

2 selection modes are available: Fusing or Limiting.

It is advisable to use the Fusing mode during the commissioning phases.

In **Fusing** mode, the drive is disabled when the current limitation threshold is reached.

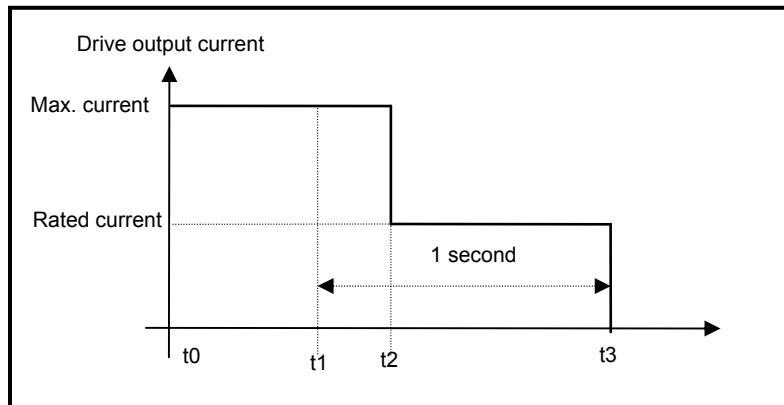

In **Limiting** mode, the motor current is only limited at the value defined by the **Rated current** parameter when the limitation threshold is reached.

### Operation of the Current Limitation in "Fusing" Mode

When the drive output RMS current ( $I^2t$ ) reaches 85 % of the rated current, the  $I^2t$  warning is displayed. If the RMS current ( $I^2t$ ) has not dropped below 85 % of the rated current within 1 second, the  $I^2t$  error is released and the drive disabled (otherwise, the  $I^2t$  warning is removed).

When the drive output RMS current ( $I^2t$ ) reaches the rated current value, the  $I^2t$  limits the drive output current at this value.

Diagram of the drive output current limitation in an extreme case (motor overloaded or shaft locked):

The maximum current duration before release of the warning is depending on the value of the parameters **Rated current** and **Max. current**. This value is calculated as follows:

$$T_{dyn} \text{ (second)} = t_1 - t_0 = 3,3 \times [\text{rated current (A)} / \text{max. current (A)}]^2 \text{ (shaft locked conditions)}$$

$$T_{dyn} \text{ (second)} = t_1 - t_0 = 10 \times [\text{rated current (A)} / \text{max. current (A)}]^2 \text{ (motor running with current frequency value higher than 2 Hz)}$$

The maximum current duration before limitation at the rated current is also depending on the value of the **Rated current** and **Max. current** parameters. This value is calculated as follows:

$$T_{max} \text{ (second)} = t_2 - t_0 = 4 \times [\text{rated current (A)} / \text{max. current (A)}]^2 \text{ (shaft locked conditions)}$$

$$T_{max} \text{ (second)} = t_2 - t_0 = 12 \times [\text{rated current (A)} / \text{max. current (A)}]^2 \text{ (motor running with current frequency value higher than 2 Hz)}$$

#### NOTE

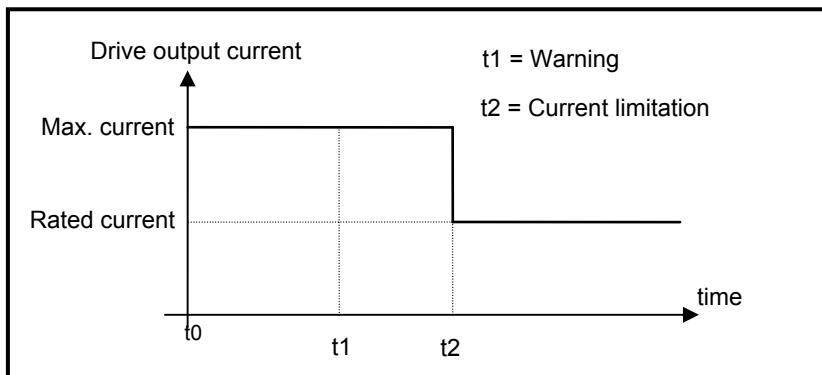

When the "Max. current / Rated current" ratio is close to 1, the  $T_{dyn}$  and  $T_{max}$  values given by the formula above are quite below the real values. But this formula remains very precise as long as the "Max. current / Rated current" ratio is higher than 3/2.

### Operation of the Current Limitation in "Limiting" Mode

When the drive output RMS current ( $I^2t$ ) reaches 85 % of the rated current, the  $I^2t$  warning is displayed. When the RMS current ( $I^2t$ ) drops below 85 % of the rated current, the  $I^2t$  warning is removed.

When the drive output RMS current ( $I^2t$ ) reaches the rated current value, the  $I^2t$  protection limits the drive output current at this value.

Diagram of the drive output current limitation in an extreme case (motor overloaded or shaft locked):

The maximum current duration before warning ( $t_1 - t_0$ ) and before limitation at the rated current ( $t_2 - t_0$ ) is calculated the same way as in the "Fusing" mode.

## **Speed limit adjustment**

The **Maximum speed** parameter defines the speed limit of the motor. This value is given in the motor catalog according to the rated supply voltage and the rated load conditions. If the drive output voltage is lower than the motor rated voltage value, the **Maximum speed** must be reduced accordingly.

The maximum value for the speed set point in the application must be adjusted in order to get a motor speed value lower than the **Maximum speed** parameter. A margin of 10 % to 20 % is recommended.

### **Current loop adjustment**

Enter the value of the total **phase-to-phase inductance** connected to the drive (motor internal winding inductance + external filtering inductance if used).

Select the current loop **Bandwidth**:

- The **High bandwidth** selection will give a high current loop gain values suitable for running high speed multi-pole motors (up to 900 Hz motor current frequency). Furthermore, the speed loop bandwidth can also be set high because the internal current loop delay is minimized. This is the default current loop bandwidth value.
- The **Low bandwidth** selection will introduce a low pass filter in the drive current measurement in order to significantly reduce the audible whistling noise with some motor technologies. In this case, the max. motor current frequency is limited at 400 Hz. The “Low bandwidth” choice for the current loop will also introduce a higher internal delay inside the speed loop. This reduces the speed loop stability margin and consequently the speed loop bandwidth.

The current loop gains are automatically calculated when the **Calculate current loop gains** command is selected.

#### **NOTE**

If the drive supply voltage value is changed, the current loop gains are automatically adjusted accordingly, inside the drive. A new calculation is not required.

### **Auto-phasing of the motor**

The **Auto-phasing** procedure identifies the motor parameters **Pole pairs**, **Phase order** and **Position sensor offset**.

- The **Pole pairs** parameter defines the number of motor pole pairs.
- The **Phase order** parameter defines the sequence of the motor phases.
- The **Position sensor offset** parameter defines the mechanical shift between the motor and the position sensor (resolver or absolute encoder) reference.

Before executing the **Auto-phasing** procedure, proceed as follows:

- Check that the values of the **Maximum current** and **Rated current** parameters are compatible with the motor. Otherwise, modify them according to the motor specifications.
- Select the I<sup>2</sup>t protection in fusing mode. The **Fusing** mode should be used for the commissioning phases.
- Uncouple the motor from the mechanical load and check that the motor shaft is free and for free rotation (1 revolution) that is not dangerous for the operator.

### 2.4.2.3 - Linear motor configuration

The **Encoder resolution** parameter is calculated as described below:

Motor pole pitch (mm)

$$\text{Encoder resolution (inc)} = 4000 \times \frac{\text{Motor pole pitch (mm)}}{\text{Encoder signal pitch (\mu m)}}$$

1 encoder signal pitch = 4 counting increments

The motor **Maximum speed** parameter value in rpm is calculated according to following formula:

$$\text{Maximum speed (rpm)} = 60 \times \frac{1000}{\text{Motor pole pitch (mm)}} \times \text{Maximum motor speed (m/s)}$$

The linear speed value in m/s is calculated according to following formula:

$$\frac{60}{\text{Motor pole pitch (mm)}} \times \frac{1000}{1000}$$

The **User position scaling** is adjusted as described below:

User position scaling = motor displacement for 1 pole pitch = Motor pole pitch (mm)

### 2.4.3 - POSITION SENSORS

The **ServoPac TT** drive has got 2 position sensor inputs: one for resolvers and a second for encoders.

Transmitter resolver type or SinCos tracks resolver type can both be connected to the drive resolver input.

Many different encoder types can also be connected to the **ServoPac TT** drive encoder input: TTL (square) signals, SinCos signals, incremental + Hall effect sensor channels, absolute encoders with HIPERFACE® communication protocol.

All internal position setpoints and displays are given by using the “user unit” definition. All internal speed setpoints and displays are given by using the “user unit / second” definition. So, it is necessary to define inside the drive the relationship between sensor data and “user unit” value.

#### Resolver input configuration

Select **Enable resolver input** if a resolver is connected to the drive. Otherwise, the **Enable resolver input** can be unselected.

Select the appropriate **Resolver type**:

- A **Transmitter** resolver is supplied by the drive modulation signal at 8 kHz. Transformation ratios from 0.3 to 0.5 are acceptable. The modulated Sine and Cosine signals of the resolver are connected to the drive resolver input.
- A **SinCos tracks** resolver is supplied by the drive +5 V sensor supply. The Sin and Cos output signals generally have an amplitude of 1 Vpp (electrically compatible with SinCos encoders) and are connected to the drive resolver input.

For a **Transmitter** resolver type:

- Enter the **Pole pairs** for a rotating resolver: number of Sine or Cosine signal periods over one shaft revolution (generally, the value is 1). This parameter affects only the motor RPM speed display.

For a **SinCos tracks** resolver type:

- Enter the **Pole pairs** for a rotating motor: number of Sine or Cosine signal periods over one shaft revolution (generally equal to the motor pole pairs).
- If the Sin and Cos signals amplitude is higher than 1 Vpp, increase the **Transformation ratio** value accordingly.
- Then move the motor manually and check that the “resolver cable interrupted” fault is not released.

Adjust the resolver **Zero mark shift** and **Zero mark width** parameter values. The resolver provides one zero mark per pole pair.

Select **Reverse position** in order to reverse the resolver counting direction, if required.

#### Encoder input configuration

Select **Enable encoder input** if an encoder is connected to the drive. Otherwise, the **Enable encoder input** can be unselected.

Select the appropriate encoder type:

- TTL encoders refer to square quadrature signals electronically compatible with RS422 standard.
- SinCos encoders refer to analog Sine and Cosine signals with 90° phase shift and 1 Vpp amplitude.
- Hall effect sensors refer to extra commutation channels for the motor current commutation. Hall effect sensor signals are adapted to the motor pole pairs.
- HIPERFACE® refers to standard communication protocols for absolute single-turn or absolute multi-turn encoders.

#### **Incremental encoder setting:**

Enter the **Zero Mark pitch** parameter value if the encoder has got a Zero mark channel. **Zero Mark pitch** is the number of encoder increments between 2 successive zero mark signals. If the encoder is not equipped with a Zero mark channel, set **Zero Mark pitch** value at 0.

Enter the **Resolution** parameter value according to the encoder mounting and the mechanical ratio for a given application.

- If the encoder is directly mounted on the motor: **Resolution** = 4 x number of encoder signal periods per shaft revolution for a rotating motor or number of encoder signal periods per pole pitch for a linear motor.
- If the encoder is coupled to the motor according to a mechanical ratio, the value of the mechanical ratio must be considered for the **Resolution** parameter calculation.

Select **Reverse direction** in order to reverse the counting direction of the encoder, if required.

Adjust the encoder **Zero mark shift** and **Zero mark width** parameter values if the encoder has got a zero mark channel.

#### **Incremental encoder + HES setting:**

Enter the **Zero Mark pitch** parameter value if the encoder has got a Zero mark channel. **Zero Mark pitch** is the number of encoder increments between 2 successive zero mark signals. If the encoder is not equipped with a Zero mark channel, set **Zero Mark pitch** value at 0.

Enter the **Resolution** parameter = 4 x number of encoder signal periods per shaft revolution for a rotating motor or number of encoder signal periods per pole pitch for a linear motor.

The parameters **HES type** and **Reverse HES tracks** are automatically calculated when the Auto-phasing procedure is performed.

Select **Reverse direction** in order to reverse the counting direction of the encoder, if required.

Adjust the encoder **Zero mark shift** and **Zero mark width** parameter values if the encoder has got a zero mark channel.

#### **Hiperface® encoder setting:**

The command **Read encoder configuration** allows reading the encoder parameter values stored in the encoder memory via the Hiperface® serial bus.

The parameter **Reverse incremental track** is manually identified according to the following procedure: move at first the motor by hand. If the error “Encoder commutation channel / incremental channel” is released when moving the motor, then toggle the parameter **Reverse incremental track**.

Select **Reverse direction** to reverse the counting direction of the encoder, if required.

#### **SinCos encoder with CD tracks setting:**

Enter the **Zero Mark pitch** parameter value if the encoder has got a Zero mark channel. **Zero Mark pitch** is the number of encoder periods between 2 successive zero mark signals x 4. If the encoder is not equipped with a Zero mark channel, set the **Zero Mark pitch** value at 0.

Enter the **Resolution** parameter = 4 x number of encoder signal periods per shaft revolution for a rotating motor or number of encoder signal periods per pole pitch for a linear motor.

The parameter **Reverse CD track** is manually identified according to the following procedure: move at first the motor manually. If the error “Encoder commutation channel / incremental channel” is released when moving the motor, then toggle the parameter **Reverse CD track**.

Select **Reverse direction** in order to reverse the counting direction of the encoder, if required.

Adjust the encoder **Zero mark shift** and **Zero mark width** parameter values if the encoder has got a zero mark channel.

#### **Position Feedback Selection**

Select the position sensor currently mounted on the motor (resolver or encoder). The position sensor mounted on the motor is used by the drive for the motor torque or force control and for the speed regulation loop.

Select the position sensor to be used for the position regulation loop in the drive, according to the application. Generally, the position regulation loop is using the motor position sensor (same sensor selection as in the previous case). However, for specific applications, the position regulation loop is using a second position sensor directly mounted on the mechanical load.

#### **User Position Scaling**

All internal position setpoints and displays are given by using the “user unit” definition. All internal speed setpoints and displays are given by using the “user unit / s” definition. So, it is necessary to define inside the drive the relationship between sensor data and “user unit” value.

Select the position unit according to the application.

Select the display factor according to the desired decimal number in the position set point and display.

Enter the load displacement value (in the previously defined position units) corresponding to one revolution for a rotating motor or one pole pitch for a linear motor. This parameter depends on the mechanical ratio between motor and load.

#### **2.4.4 - SERVO LOOPS ADJUSTMENT**

The **ServoPac TT** drive speed and position loop gain values can be automatically calculated by using the Auto-tuning procedure. This procedure identifies the motor and mechanical load specifications and calculates the appropriate gain values.

The Auto-tuning procedure can be executed with the drive disabled or enabled (for a vertical load). When the drive is enabled, the Auto-tuning can only be executed if the motor is at standstill.

##### **Auto-tuning of the drive regulator**

Select the **Controller type** according to the application:

- In Velocity mode, only the speed loop gains are calculated.
- In Position mode, all gains of both speed and position regulators are calculated.

Select the **Position loop requirements** if the position mode was selected before:

- The choice **Minimum following error** allows getting an accurate following of the position reference value during the whole motor displacement. In this case, all feedforward gain values are calculated.
- The choice **Minimum position overshoot** allows getting a motor positioning without any overshoot of the target position. In this case, all feedforward gain values are set at 0, and the motor position is lagging with regard to the position reference value during the whole motor displacement.

Select the **Speed measurement** filter time constant according to the motor position sensor resolution and the acceptable noise level in the speed measurement. The higher the time constant value, the lower the speed measurement noise, but also the lower the speed loop gains because of the increased speed measurement delay.

When **Auto-select** is selected, the most appropriate value is chosen during the Auto-tuning procedure execution.

Select the servo loop **Filter type** according to the application:

- The choice of the **Anti-resonance** filter is necessary in case of loud noise in the motor, due to motor/load coupling elasticity.
- The choice of the **Maximum stiffness** filter allows getting the maximum stiffness on the motor shaft with regard to the torque disturbances. However, this choice is only possible without any resonance due to the motor/load coupling elasticity.

Select the desired closed loop **Bandwidth** (cut-off frequency value of the closed loop frequency response) according to the dynamic performances requirements of the application (Low = 50 Hz, Medium = 75 Hz, High = 100 Hz).

- **High** bandwidth means short response time of the servo loop and high gain values.
- **Low** bandwidth means larger response time of the servo loop and lower gain values.

Before executing the Auto-tuning procedure, check that the motor shaft is free and that its rotation over one revolution is not dangerous for operator and machine. Check also that the brake is released (the Auto-tuning command does not control the brake).

After the Auto-tuning, in case of loud noise in the motor at standstill or when running, check the rigidity of the mechanical transmission between motor and load (backlashes and elasticity in motor and couplings). If required, start a new Auto-tuning procedure by selecting a lower Bandwidth. If the instability remains, start a new Auto-tuning procedure by activating the Anti-resonance filter. If necessary, adjust more accurately the loop response stability by adjusting the Gain scaling factor.

In case of loud noise in the motor, only when running, during the acceleration and deceleration phases, set **Feedforward acceleration gain** value at 0.

In the case of an axis with vertical load, proceed as follows:

- Select the **Limiting** current limitation mode (in order to avoid the drive being disabled in case of an  $I^2t$  protection release).

- Initialize the speed loop gains corresponding to the unloaded motor (execute therefore the Auto-tuning procedure with the motor uncoupled from its mechanical load).
- Couple the motor to its load. If possible, make a control in speed mode; otherwise, close the position loop with a stable gain.
- Move the axis until a stall position where one motor revolution is not dangerous for operator and machine (far enough from the mechanical stops).
- Then execute the Auto-tuning procedure with the motor at standstill. If the axis is moving, the Auto-tuning procedure has not been accepted by the drive.

### Regulator gains

**Speed loop** gains are the most critical to adjust because they greatly depend on the mechanical load characteristics (inertias, frictions, coupling stiffness, resonances,...).

- **Proportional speed gain (KPv)**: defines the proportional gain of the controller which acts on the speed error. The higher this parameter value, the faster the speed loop response.
- **Integral speed gain (KIV)**: defines the integral gain of the controller which acts on the speed error. The higher this parameter value, the better the axis stiffness.
- **Integrator low frequency limit (Klvf in Hz)**: defines the low frequency value from where the controller integrator term is saturated. This parameter is used for reducing the motor heating in applications with large dry frictions due to the mechanical load.
- **Damping gain (KCv)**: defines the proportional gain of the controller which acts only on the speed feedback. This parameter allows reducing the speed loop overshoot in response to a step-like set point change.
- **Derivative speed gain (KDv)**: defines the derivative gain of the controller which acts on the speed error.
- **Derivator high frequency limit (KDvf in Hz)**: defines the high frequency value from which the controller derivative term is saturated.
- **Gain scaling factor (KJv)**: defines a multiplying factor for all speed regulator gains. This parameter scales the speed regulator gains in order to avoid any saturation when high values are required. This parameter also allows adjusting the servo loop stability in case of load inertia changes.

The **Current command filter** is a 3rd order, low-pass type filter, with 3 adjustable cut-off frequencies. Each cut-off frequency value can be freely adjusted according to the application for the filtering of high frequency noise or the filtering of mechanical resonances.

The **Speed measurement filter** is a 1st order, low-pass type filter, with 3 selectable time constant values. The higher the time constant value, the lower the speed measurement noise, but also the lower the speed loop gains because of the increased speed measurement delay. The **Speed measurement filter** time constant is selected according to the motor position sensor resolution and the acceptable noise level in the speed measurement.

**Position loop** gains mainly influence the servo motor behaviour during the displacements (following error, position overshoot, audible noise, ...).

- **Proportional position gain (KPp)**: defines the proportional gain of the controller which acts on the position error. The higher this parameter value, the better the axis stiffness and the lower the following error.
- **Feedforward speed 1 gain (KFp)**: defines the feedforward speed amplitude corresponding to the speed input command. This term allows reducing the following error during the motor displacement. Its value is set at maximum (65536) after the autotuning procedure, if a following error as small as possible is required.
- **Feedforward speed 2 gain (KBv)**: defines the feedforward speed amplitude corresponding to the viscous frictions. This term allows reducing the viscous friction effect during the motor displacement. The gain value is equal to the damping gain value + the viscous friction compensation term. After the auto-tuning procedure, the feedforward speed 2 gain is set equal to the damping gain value, if a following error as small as possible is required. The viscous friction compensation term can be calculated by measuring the current/speed ratio at various motor speed values.

**- Feedforward acceleration gain (KAv):** defines the feedforward acceleration amplitude corresponding to the acceleration input command. This term allows reducing the following error during the motor acceleration and deceleration phases. Its value is calculated by the amplifier during the auto-tuning procedure if a following error as small as possible is required.

When the **auto-tuning** procedure is executed, the motor + mechanical load specifications are identified and the appropriate gain values are calculated according to the requirements selected by the user (controller type, filter type, bandwidth value, ...). All gain values can then be manually modified by the user, if required.

### Following error

**Speed error threshold** defines the speed following error triggering threshold. It is important to correctly adjust this value in order to get a good protection of the drive and the application.

The **Speed error threshold** parameter can be adjusted like follows:

- Get the motor running with the required operation cycles and measure the maximum value of the speed error in the digital oscilloscope (Max. speed error value);
- Then set the **Speed error threshold** parameter = 1.3 to 1.5 x Max. speed error value.

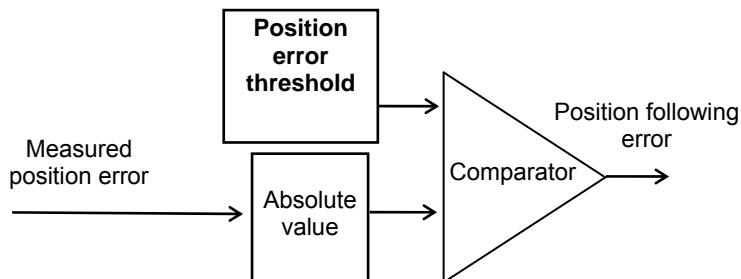

**Position error threshold** defines the triggering threshold of the position following error. It is important to correctly adjust this value in order to get a good protection of the drive and the application.

The **Position error threshold** parameter can be adjusted like follows:

- Make the motor running with the required operation cycles and measure the maximum value of the following error in the digital oscilloscope (max. following error value);
- Then set the **Position error threshold** parameter = 1.3 to 1.5 x Max. following error value.

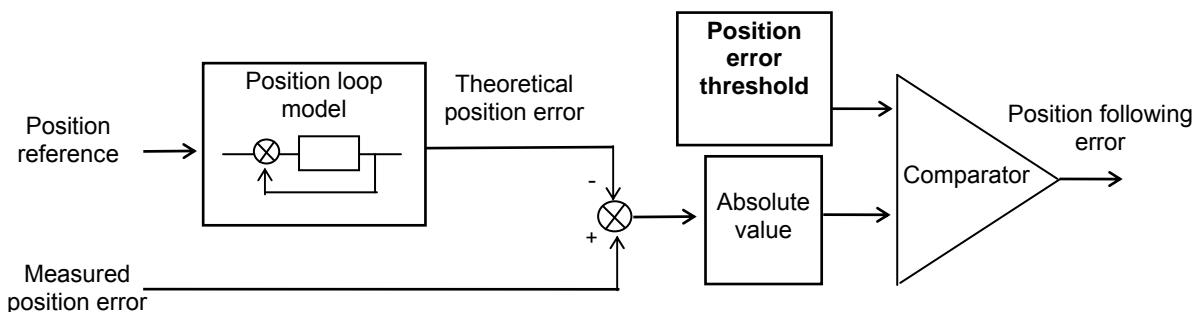

The **Position error detection mode** defines the operation mode of the axis following error protection.

- When **Absolute** is selected, the following error protection is operating as described below:

The measured position error value is continuously compared with the **Position error threshold** parameter value. When the measured position error is exceeding the **Position error threshold**, the position following error is released. This configuration is used for applications requiring the smallest possible following error.

- When **Relative to dynamic model** is selected, the following error protection is operating as described below:

The measured position error value is continuously compared with the theoretical position error given by the position loop model. When the difference is exceeding the **Position error threshold**, the position following error is released. In this configuration, when the position servo loop is adjusted to get the motor position continuously lagging the reference position (applications for positioning without overshoot and with a high following error value), any small anomaly in the actuator behaviour can be detected.

#### **2.4.5 - CONFIGURATION OF THE DRIVE ENABLE**

When "Enable control by **SOFTWARE**" is selected, the drive is enabled and disabled by using the control word (On/Off command in GemDriveStudio or fieldbus control).

When "Enable control by **HARDWARE**" is selected, the drive is enabled and disabled by using the ENABLE logic input.

#### **2.4.6 - QUICK TEST OF THE SERVO DRIVE**

The loop stability can be tested on-line by moving the motor in speed profile mode or in position profile mode. The regulator gains can be manually optimized or by using the auto-tuning procedure.

##### **Profile Velocity parameters**

Enter the **Maximum velocity** parameter value according to the motor **Maximum speed** and the limitation due to the mechanical load in the application. For the first tests, a reduced velocity range is preferred in order to prevent hazardous movements with wide amplitude. This parameter is active in both velocity profile mode and position profile mode.

Enter the **Acceleration** and **Deceleration** parameter values. Small values can be used as a starting point in order to prevent sharp movements on the mechanical load. This parameter is active in both velocity profile mode and position profile mode.

##### **Profile Position parameters**

Enter the **Maximum velocity** parameter value according to the motor **Maximum speed** and the limitation due to the mechanical load in the application. For the first tests, a reduced velocity range is preferred in order to prevent hazardous movements with a large amplitude. This parameter is active in both velocity profile mode and position profile mode.

Enter **Acceleration** and **Deceleration** parameter values. Small values can be used as a starting point in order to prevent sharp movements on the mechanical load. This parameter is active in both velocity profile mode and position profile mode.

Enter the **Profile velocity** parameter value according to the desired motor displacement speed. The **Profile velocity** parameter value must be lower than or equal to the **Maximum velocity** parameter value.

##### **Checking the servo loop stability**

In velocity mode:

Disable the motor brake, enable the drive, and check the servo loop stability at standstill: in case of loud noise in the motor, check the rigidity of the mechanical transmission between motor and load (backlashes and elasticity in motor and couplings). If required, start a new **Auto-tuning** procedure by selecting a lower **Bandwidth**. If the instability remains, start a new **Auto-tuning** procedure by activating the **Anti-resonance** filter. If necessary, adjust more accurately the servo loop stability by adjusting the **Gain scaling factor**.

Move the axis in both directions (low velocity set point value), and check the servo loop stability in movement: in case of loud noise in the motor during the displacement, the **Speed measurement filter** time constant can be increased. For high frequency noise or mechanical resonances, use the 3rd order low-pass **Current command filter** and adjust the 3 cut-off frequencies with the most appropriate values.

Move the axis in both directions (higher velocity set point value), and check the servo loop time response. In case of undesired overshoot for a step-like velocity set point change, increase the **Damping speed gain** value and reduce the **Proportional speed gain** value accordingly.

### In position mode:

Disable the motor brake, enable the drive, and check the servo loop stability at standstill: in case of loud noise in the motor, check the rigidity of the mechanical transmission between motor and load (backlashes and elasticity in motor and couplings). If required, start a new **Auto-tuning** procedure by selecting a lower **Bandwidth**. If the instability remains, start a new **Auto-tuning** procedure by activating the **Anti-resonance** filter. If necessary, adjust more accurately the servo loop stability by adjusting the **Gain scaling factor**.

Move the axis in both directions with a low **Profile velocity** value, and check the servo loop stability in movement. In case of loud noise in the motor during the displacement, the **Speed measurement filter** time constant can be increased. For high frequency noise or mechanical resonances, use the 3rd order low pass **Current command filter** and adjust the 3 cut-off frequencies with the most appropriate values.

Move the axis in both directions with a higher **Profile velocity** value and check the motor positioning behaviour. In case of loud noise in the motor during the acceleration and deceleration phases, set **Feedforward acceleration gain** value at 0. In case of undesired position overshoot at the end of the deceleration phase, reduce the **Feedforward speed 1** value.

### **NOTE**

In Profile velocity mode, only the speed regulator gains are active.

In Profile position mode, all gains of both speed and position regulators are active. However, if the Auto-tuning was executed in Velocity mode, all position loop gains are equal to 0 and the motor cannot move.

In Interpolated Position Mode, Feedforward Acceleration Gain must be manually cleared after Auto-tuning procedure.

## **2.4.7 - LOGIC INPUTS**

**ServoPac TT** drives offer the use of built-in functions for the drive operation. These functions can be controlled by using "logical signal" or digital input. The default configuration is "logical signal". If required, any digital input can be connected to a given function for the hardware control.

### **"ENABLE" INPUT**

This function allows enabling and disabling the drive when the "Enable control by HARDWARE" is selected.

Note: when a digital input is connected to this function for the hardware control, it is recommended to use a 24 Vdc signal on the input to enable the drive by choosing the appropriate value for the polarity parameter.

### **"INHIBIT" INPUT**

The INHIBIT input must be deactivated in order to enable the drive by using the control word, when the "Enable control by SOFTWARE" is selected. Activating the INHIBIT input during the operation will disable the drive.

Note: when a digital input is connected to this function for the hardware control, it is recommended to use a 0 Vdc signal on the input to inhibit the drive by choosing the appropriate value for the polarity parameter.

### **"LIMIT SWITCH" INPUT**

The "Limit switch" inputs are inputs for a detection sensor that allows stopping the motor with maximum deceleration. The purpose of both limit switches, when they are mounted at the right place on the axis stroke, is to protect the mechanics in case of uncontrolled movements.

The limit switches are only defined according to the motor hardware rotation. They are independent from the "rotation/counting direction" selection.

For checking the wiring of the limit switch inputs:

- move the motor in one direction,
- activate the limit switch placed in the rotation direction (artificially, if necessary),
- then check the motor stopping; if the motor goes on moving, reverse the wiring of the limit switch inputs.

### Notes:

- When activating a limit switch input, the motor is stopped with maximum deceleration.
- The limit switch inputs must be setup to be activated if disconnected from the +24 V potential.

### **"HOME SWITCH" INPUT**

In Homing mode, according to the machine structure, it may be necessary to connect a digital sensor to identify the real position of an axis. In this case, a digital I/O has to be connected to this function. Home switch input is also a possible input for the capture function.

**“CAPTURE” INPUT**

The Capture function allows recording motor position and/or second sensor measurement when an external signal is changing.

**“QUICK STOP” INPUT**

Activating the QUICK STOP input during the operation makes the axis decelerate. At the end of the deceleration, the motor is maintained enabled at standstill.

**“START PHASING” INPUT**

The START PHASING input allows starting the motor phasing procedure at the drive power up when the motor is equipped with an incremental encoder without HES.

**“ERROR RESET” INPUT**

The ERROR RESET input allows erasing a released drive fault when the cause of the fault release is eliminated.

**“SEQ START” INPUT**

The SEQ START input allows starting the selected sequence when the drive Sequence mode is selected.

**“SEQ STOP” INPUT**

The SEQ STOP input allows stopping any sequence execution when the drive Sequence mode is selected.

**“SEQ SEL 1” INPUT**

The SEQ SEL 1 input is connected to bit 0 of the sequence number selection when the drive Sequence mode is selected.

**“SEQ SEL 2” INPUT**

The SEQ SEL 2 input is connected to bit 1 of the sequence number selection when the drive Sequence mode is selected.

**“SEQ SEL 3” INPUT**

The SEQ SEL 3 input is connected to bit 2 of the sequence number selection when the drive Sequence mode is selected.

**“SEQ SEL 4” INPUT**

The SEQ SEL 4 input is connected to bit 3 of the sequence number selection when the drive Sequence mode is selected.

**“SEQ COND 1” INPUT**

The SEQ COND 1 input can be used as a start condition or an end condition for a sequence when the drive Sequence mode is selected.

**“SEQ COND 2” INPUT**

The SEQ COND 2 input can be used as a start condition or an end condition for a sequence when the drive Sequence mode is selected.

**“SEQ COND 3” INPUT**

The SEQ COND 3 input can be used as a start condition or an end condition for a sequence when the drive Sequence mode is selected.

**“SEQ COND 4” INPUT**

The SEQ COND 4 input can be used as a start condition or an end condition for a sequence when the drive Sequence mode is selected.

## 2.4.8 - LOGIC OUTPUTS

Any drive state signal can be connected to a digital output.

### "BRAKE" OUTPUT

This signal is useful for the motor brake control when the drive is enabled or disabled.

### "FAULT" OUTPUT

This signal indicates that a fault is released inside the drive.

### "WARNING" OUTPUT

This signal indicates that a warning is released inside the drive.

### "UNDERVOLTAGE WARNING" OUTPUT

This signal indicates that the DC bus voltage value is dropping below the "Undervoltage Warning Threshold" parameter value.

### "VOLTAGE ENABLED" OUTPUT

This signal indicates that the drive is powered (Undervolt. is over).

### "PHASING NOT OK" OUTPUT

This signal indicates that the motor is not ready to be enabled because a phasing or auto-phasing procedure is required.

### "DRIVE ON" OUTPUT

This signal indicates that the motor is enabled and under servo control.

### "IN POS" OUTPUT

This signal indicates that the motor has reached the target position when the drive Profile position or Sequence mode is selected.

### "SEQ", "POS", "SPEED", "OUT1", "OUT2", "OUT3", "OUT4" OUTPUTS

These signals concern the sequence execution when the drive Sequence mode is selected.

### "PULSE RX" OUTPUT

This signal indicates that a pulse train is received on the PULSE input when the drive Stepper emulation mode is selected.

## 2.4.9 - LOGIC I/Os EXTENSION

The external CANopen I/Os module extension is supported by the TT-CAN version of the servo drive. The external I/Os module is connected to the CAN bus on the same network as the servo drive. When many servo drives are connected on the CAN bus, a given I/Os module can only be assigned to one servo drive.

The basic setup of an external I/Os module is the following:

- adjust first the I/Os module baudrate equal to the servo drive baudrate,
- adjust also the address of the I/Os module on the CAN bus network,
- then select the address of the I/Os module in the servo drive configuration window,
- connect the servo drive to the I/Os module.

The default setting is the following:

- SDO communication between the servo drive and I/Os module,
- module inputs 1 to 5 are assigned to the virtual drive inputs IN6 to IN10,
- module outputs 1 to 3 are assigned to the virtual drive outputs OUT4 to OUT6.

## 2.4.10 - BRAKING RESISTOR

When the drive is operating in standalone mode (AC main connection without GDPS), select the correct braking resistor operation according to the drive configuration on the X9 connector. If the drive is operating with a GDPS power supply (DC bus connection), the drive braking resistor parameters are not valid.

- When the **Internal braking resistor** operation is selected the **Duty cycle limit** parameter value is limited at 25 per thousand. This means a maximum braking transistor conduction of 25 ms over a period of 1 second. This selection allows protecting the drive internal 35W braking resistor against overheating and failure.
- When the **External braking resistor** operation is selected the **Duty cycle limit** parameter value is limited at 70 per thousand. This means a maximum braking transistor conduction of 70 ms over a period of 1 second.

The parameter **Braking resistor duty cycle limit** allows limiting the external braking resistor average power in order to protect it against overheating and failure. The **Duty cycle limit** parameter value is calculated according to the external braking resistor specifications as described below:

Duty cycle limit = Braking resistor rated power (W) x Braking resistor ohmic value (Ohms) / Braking on threshold (V) / Braking off threshold (V).

## 2.5 - DRIVE PARAMETER SAVING

When all adjustments and settings have been tested, they can be stored in the non-volatile drive memory by selecting the command **Drive parameter file > Store parameters to flash memory**. In this case, all drive standard parameters are saved in the drive file DRIVEPAR.TXT.

The drive file DRIVEPAR.TXT can then be transferred to the project directory in the PC by selecting the command **Drive parameter file > Backup parameters to PC file**.

The command **Drive parameter file > Restore parameters** allows transferring a file DRIVEPAR.TXT saved in the PC directory to the drive.

A user parameter list can also be edited and saved in the file USER\_PAR.TXT by using the command **User parameter file > Edit Parameters**. The USER\_PAR.TXT file can then be transferred to the drive by selecting the command **User parameter file > Restore parameters**. A drive file USER\_PAR.TXT can be transferred from the drive to the PC directory by selecting the command **User parameter file > Backup parameters to PC file**. The user parameter file USER\_PAR.TXT can be used for saving drive parameters that are not saved in the file DRIVEPAR.TXT (standard drive parameter list).

Note: The commands **Tools > Drive file backup** and **Tools > Drive file restoring** concern all project drive files: DRIVEPAR.TXT, USER\_PAR.TXT, SEQUENCE.TXT, and so on.

## 2.6 - OSCILLOSCOPE

The oscilloscope can be launched in the **Gem Drive Studio** software or in stand-alone mode.

This oscilloscope allows displaying any drive signal by using the Index / Sub-index identification.

Four different channels are available to display signals. Multi-axis channel operation can be selected.

See **Gem Drive Studio Quick Start** manual for more details.

## 2.7 - DIALOG TERMINAL

The dialog terminal can be launched in the **Gem Drive Studio** software or in stand-alone mode.

This terminal allows:

- Reading a parameter value on a selected axis (continuous value monitoring can also be performed).
- Writing a parameter value on a selected axis.

It is possible to read and/or write parameters on 4 different axes at the same time.

See **GemDriveStudio** Quick Start manual for more details.

| hm               | Homing Mode.                                                                                                                                                |
| ip               | Interpolated Position Mode.                                                                                                                                 |
| tq               | Profile Torque Mode.                                                                                                                                        |
| pc               | Position Control Function.                                                                                                                                  |
| ServoPac         | Generic name of the TRANSTECHNIK servo drive family with resolver and encoder feedback input.                                                               |
| Numerical value  | Hexa is preceded by 0x, decimal otherwise                                                                                                                   |
| Dynamic Variable | Element of an object indicated by index and sub-index which can be mapped in a PDO.<br>An element of an object is addressed by its index and its sub-index. |

**Dataflow** An element of an object is qualified as dataflow (signal) if it is a variable (i.e. mappable). These variables can be of 8 bit, 16 bit or 32 bit. Depending on the using context, a dataflow must be of 16 bit or 32 bit or any size.

The dataflow can be issued from:

- An external source:  
Examples : Encoder position 0x3129-0  
 Analog Input 0x31F1-1 (16 bit)  
 Analog Input 0x31F1-2 (32 bit)
- The CAN bus:  
Example: Interpolated data 0x30C1-0 (32 bit)
- An internal signal:  
Examples: Profile Speed Function Block output 0x3526-0 (32-bit)  
 User variable : 0x3710-3 (32-bit)

### 3.1 - CANOPEN COMMUNICATION

#### 3.1.1 - COMMUNICATION OBJECTS

##### 3.1.1.1 - CAN Telegram

CAN TELEGRAM

|     |        |     |      |              |     |     |     |

CRC Cyclic Redundancy Check

ACK Acknowledge

EOM End Of Message

##### 3.1.1.2 - Default COB-ID

The COB-ID is of 11 bits. Node-ID (bits 0 - 6) is the drive address from 1 to 127.

|               |   |   |   |   |         |   |   |   |   |   |
|---------------|---|---|---|---|---------|---|---|---|---|---|
| 10            | 9 | 8 | 7 | 6 | 5       | 4 | 3 | 2 | 1 | 0 |
| Function Code |   |   |   |   | NODE-ID |   |   |   |   |   |

**Default COB-ID:**

Broadcast objects of the pre-defined connection set:

| Object | Function Code | Resulting COB-ID | Communication Parameter at Index |
|--------|---------------|------------------|----------------------------------|
| NMT    | 0000          | 0                | -                                |
| SYNC   | 0001          | 128 (80h)        | 1005h, 1006h, 1007h              |

Peer-to-peer objects of the pre-defined connection set:

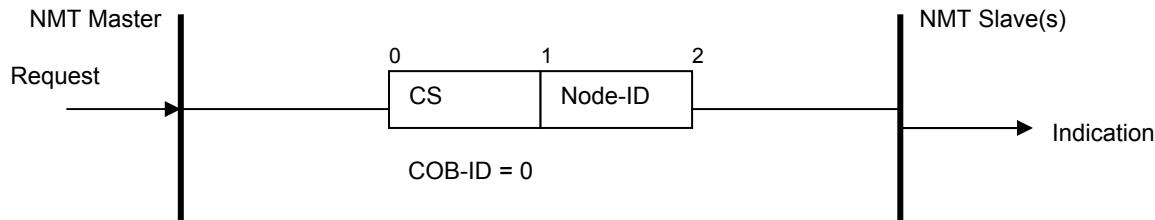

| Object    | Function Code | Resulting COB-ID          | Communication Parameter at Index |
|-----------|---------------|---------------------------|----------------------------------|
| EMERGENCY | 0001          | 129 (81h) - 255 (FFh)     | 1014h                            |
| PDO1 (TX) | 0011          | 385 (181h) - 511 (1FFh)   | 1800h                            |
| PDO1 (RX) | 0100          | 513 (201h) - 639 (27Fh)   | 1400h                            |
| PDO2 (TX) | 0101          | 641 (281h) - 767 (2FFh)   | 1801h                            |
| PDO2 (RX) | 0110          | 769 (301h) - 895 (37Fh)   | 1401h                            |
| PDO3 (TX) | 0111          | 897 (381h) - 1023 (3FFh)  | 1802h                            |
| PDO3 (RX) | 1000          | 1025 (401h) - 1151 (47Fh) | 1402h                            |
| PDO4 (TX) | 1001          | 1153 (481h) - 1279 (4FFh) | 1803h                            |
| PDO4 (RX) | 1010          | 1281 (501h) - 1407 (57Fh) | 1403h                            |
| SDO (TX)  | 1011          | 1409 (581h) - 1535 (5FFh) | 1200h                            |
| SDO (RX)  | 1100          | 1537 (601h) - 1663 (67Fh) | 1200h                            |

TX = Transmit from drive to master

RX = Receive by drive from master

### 3.1.1.3 - Network Management Objects

#### NMT Protocols

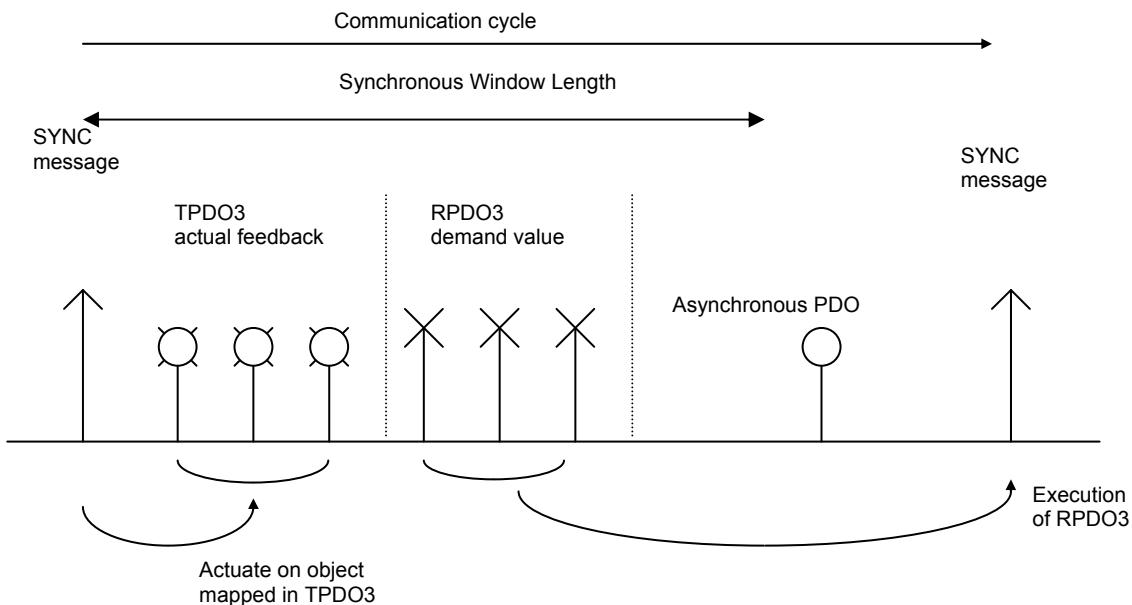

| NMT Protocol          | Command Specifier CS | Remarks                         |
|-----------------------|----------------------|---------------------------------|
| Start Remote Node     | 1                    | Change to NMT Operational state |
| Stop Remote Node      | 2                    | Change to NMT Stop state        |
| Enter Pre-Operational | 128                  |                                 |
| Reset Node            | 129                  |                                 |
| Reset Communication   | 130                  |                                 |

Node-ID: The Node-ID indicates the address of the drive. If Node\_ID = 0, the protocol addresses all NMT slaves.

### 3.1.1.4 - Synchronisation Object

The SYNC object is a broadcast message sent by the master. This message provides a network clock. The period is specified by the communication cycle period (object 0x1006). The ServoPac TT drives use this SYNC message to synchronize their local clock.

At least 180 ms are necessary for the servo-drive to start the synchronisation.

### COB-ID Sync Message

| Index         | 0x1005              |
|---------------|---------------------|
| Name          | COB-ID Sync Message |
| Object Code   | VAR                 |
| Data Type     | Unsigned32          |
| Object Class  | all                 |
| Access        | rw                  |
| PDO Mapping   | No                  |
| Default Value | 0x00000080          |

This object defines the COB-ID of the synchronisation object (SYNC).

The ServoPac TT drive does not support 29-bit ID.

| Bit number | Value | Meaning                               |
|------------|-------|---------------------------------------|
| 31 (MSB)   |       | No Bootup message                     |
| 30         | 0     | Device does not generate SYNC message |
|            | 1     | Device generates SYNC message         |
| 29         | 0     | 11-bit ID (CAN 2.0 A)                 |
| 28-11      | 0     |                                       |
| 10-0 (LSB) | x     | bits 10-0 of SYNC COB-ID              |

## Communication Cycle Period

| Index         | 0x1006                                                    |
|---------------|-----------------------------------------------------------|
| Name          | Communication Cycle Period                                |
| Object Code   | VAR                                                       |
| Data Type     | Unsigned32                                                |
| Access        | rw                                                        |
| PDO Mapping   | No                                                        |
| Unit          | μs                                                        |
| Value Range   | 0..20000 (only the values multiples of 500 are supported) |
| Default Value | 10000                                                     |

This object defines the communication cycle. This period is also used for the synchronisation in interpolated position mode. When the value of this object is reset at 0, the synchronisation is no more operative.

## Sync Control

A PLL allows the internal cycle to be synchronized on SYNC message.

This object allows adjusting the PLL parameters.

| Index              | 0x2006       |
|--------------------|--------------|
| Name               | Sync control |
| Object Code        | ARRAY        |
| Number of Elements | 4            |

### Value Description

|               |                                                                    |
|---------------|--------------------------------------------------------------------|

### 3.1.1.5 - Process Data Objects (PDO)

PDOs are unconfirmed messages used for real-time data exchange.

PDOs sent by the master are RPDOs and PDOs sent by the drive are TPDOs.

Data in each PDO are defined by a list of objects (PDO mapping).

There are 4 PDOs: TPDO1, RPDO1, TPDO2, RPDO2, TPDO3, RPDO3, TPDO4 and RPDO4.

Each PDO is defined by:

PDO communication parameters with:

- object 0x1400, 0x1401, 0x1402, 0x1403 for RPDOs
- object 0x1800, 0x1801, 0x1802, 0x1803 for TPDOs

PDO mapping with:

- object 0x1600, 0x1601, 0x1602, 0x1603 for RPDOs
- object 0x1A00, 0x1A01, 0x1A02, 0x1A03 for TPDOs

#### Communication parameters

Communication parameters are:

- PDO COB-ID,
- Transmission type

The distribution of COB-ID is defined by default. The modification of COB-ID of PDO can be made in *NMT Pre-Operational State*; the new COB-ID will take effect when the NMT state machine switches to *Operation State*. The modification must not be taken in *NMT Operational State*, otherwise a *Reset\_Communication* will be necessary before the new COB-ID takes effect.

Transmission type supported by the ServoPac TT servo drive:

| Transmission type | PDO transmission                 |         |                                  |                                  |                                  |
|-------------------|----------------------------------|---------|----------------------------------|----------------------------------|----------------------------------|
|                   | cyclic                           | acyclic | synchronous                      | asynchronous                     | RTR only                         |
| 1                 | TPDO1<br>TPDO2<br>TPDO3<br>TPDO4 |         | TPDO1<br>TPDO2<br>TPDO3<br>TPDO4 |                                  |                                  |
| 2-240             |                                  |         |                                  |                                  |                                  |
| 253               |                                  |         |                                  |                                  | TPDO1<br>TPDO2<br>TPDO3<br>TPDO4 |
| 254               |                                  |         |                                  |                                  |                                  |
| 255               |                                  |         |                                  | TPDO1<br>TPDO2<br>TPDO3<br>TPDO4 |                                  |

- Transmission types 1 - 240 are synchronous transmissions with regard to the SYNC messages. A value between 1 and 240 means that the PDO is synchronously and cyclically transferred. The transmission type indicates the numbers of SYNC which are necessary to trigger PDO transmissions.
- Transmission type 253 means that the PDO is only transmitted on remote transmission request.
- Transmission type 255 is event trigger: The PDO will be transmitted when the first object (must be 16-bit) mapped in PDO has changed.

#### PDO transmission modes:

- *Synchronous*: the message is transmitted in synchronisation with the SYNC message. A synchronous message must be transmitted within a pre-defined time-window immediately after the SYNC message.
- *Asynchronous*: the message is sent independently of the SYNC message.

#### Triggering modes:

- *Event\_Driven*:  
Message transmission by reception of SYNC.  
Message transmission by specific event.
- *Remotely requested*: the transmission of an asynchronous PDO is initiated at reception of a remote request by any other device.

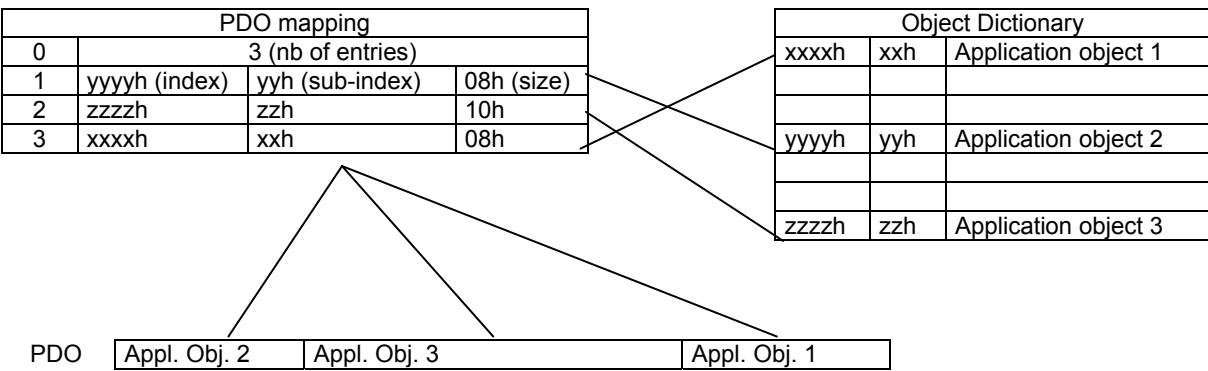

#### **PDO Mapping**

The sub-index 0 of mapping parameter contains the number of valid entries within the mapping record. This number of entries is also the number of application variables which shall be transmitted/received with the corresponding PDO. The sub-index 1 to number of entries contains the information about the mapped application variables. These entries describe the PDO contents by their index, sub-index and length (in bits).

Structure of PDO Mapping Entry:

|        |                |                                         |
|--------|----------------|-----------------------------------------|
| Byte : | MSB            | LSB                                     |
|        | index (16 bit) | sub-index (8 bit) object length (8 bit) |

Principle of PDO mapping:

### Multiplexed data

The multiplexed data is used to multiplex more than one axis demand value into one message RPDoN. It is possible to send 4 axis demand values (16 bit absolute) with one RPDoN. Therefore, the controller must modify the COB-ID of RPDoN of each axis to the same cob-ID. For example (see also the following diagram), for axis 1, object 60C1-1 is mapped into the first mapped object (object 1602-1), for axis 2, object 60C1-1 is mapped into the 2nd mapped object (object 1602-2) and so on... For each axis, the balance of the mapped objects must be mapped with a dummy object.

A dummy object mapped is realized with objects:

- 0x0002 (integer8)
- 0x0003 (integer16)
- 0x0004 (integer32)
- 0x0005 (unsigned8)
- 0x0006 (unsigned16)
- 0x0007 (unsigned32)

These objects can be used to map a PDO as a dummy object but cannot be accessed via SDO (see DS-301, 9.5.3 Data type entry specification).

### Example of multiplexed data:

| TPDO Cob-ID<br>0x501 | MSB | Data_Ax4 (16bit) | Data_Ax3 (16bit) | Data_Ax2 (16bit) | LSB<br>Data_Ax1 (16bit) |
|----------------------|-----|------------------|------------------|------------------|-------------------------|
|----------------------|-----|------------------|------------------|------------------|-------------------------|

This PDO is transmitted with COB-ID 0x501 and contains 16bits x 4 of data

| Object                                        | Value      |
|-----------------------------------------------|------------|
| RPDO1 COB-ID (object 1400-1)                  | 0x501      |
| Number of mapped objects (object 1600-0)      | 0x1        |
| 1 <sup>st</sup> Mapped Object (object 1600-1) | 0x60C10110 |

In drive 1, "Data\_Ax1" will be written in object 60C1-1

| Object                                        | Value              |
|-----------------------------------------------|--------------------|
| RPDO1 COB-ID (object 1400-1)                  | 0x501              |
| Number of mapped objects (object 1600-0)      | 0x2                |
| 1 <sup>st</sup> Mapped Object (object 1600-1) | 0x00060010 (dummy) |
| 2 <sup>nd</sup> Mapped Object (object 1600-2) | 0x60C10110         |

In drive 2, "Data\_Ax2" will be written in object 60C1-1

| Object                                        | Value              |
|-----------------------------------------------|--------------------|
| RPDO1 COB-ID (object 1400-1)                  | 0x501              |
| Number of mapped objects (object 1600-0)      | 0x3                |
| 1 <sup>st</sup> Mapped Object (object 1600-1) | 0x00060010 (dummy) |
| 2 <sup>nd</sup> Mapped Object (object 1600-2) | 0x00060010 (dummy) |
| 3 <sup>rd</sup> Mapped Object (object 1600-3) | 0x60C10110         |

In drive 3, "Data\_Ax3" will be written in object 60C1-1

| Object                                        | Value              |
|-----------------------------------------------|--------------------|
| RPDO1 COB-ID (object 1400-1)                  | 0x501              |
| Number of mapped objects (object 1600-0)      | 0x4                |
| 1 <sup>st</sup> Mapped Object (object 1600-1) | 0x00060010 (dummy) |
| 2 <sup>nd</sup> Mapped Object (object 1600-2) | 0x00060010 (dummy) |
| 3 <sup>rd</sup> Mapped Object (object 1600-2) | 0x37100110         |
| 4 <sup>th</sup> Mapped Object (object 1600-4) | 0x60C10110         |

In drive 4, “Data \_Ax4” will be written in object 60C1-1 and “Data \_Ax3” in object 3710-1

## Receive PDO Communication Parameter

### Object 0x1400: 1st Receive PDO Communication Parameter

| Index              | 0x1400                                          |
|--------------------|-------------------------------------------------|
| Name               | 1st Receive PDO Communication Parameter (RPDO1) |
| Object Code        | RECORD                                          |
| Number of Elements | 2                                               |

#### Value Description

|               |                 |
|---------------|-----------------|
| Sub Index     | 1               |
| Description   | COB-ID          |
| Data Type     | Unsigned32      |
| Access        | rw              |
| PDO Mapping   | No              |
| Default Value | 0x200 + Node-ID |

|               |                   |
|---------------|-------------------|
| Sub Index     | 2                 |
| Description   | Transmission Type |
| Data Type     | Unsigned8         |
| Access        | rw                |
| PDO Mapping   | No                |
| Default Value | 253               |

### Object 0x1401: 2nd Receive PDO Communication Parameter

| Index              | 0x1401                                          |
|--------------------|-------------------------------------------------|
| Name               | 2nd Receive PDO Communication Parameter (RPDO2) |
| Object Code        | RECORD                                          |
| Number of Elements | 2                                               |

#### Value Description

|               |                 |
|---------------|-----------------|
| Sub Index     | 1               |
| Description   | COB-ID          |
| Data Type     | Unsigned32      |
| Access        | rw              |
| PDO Mapping   | No              |
| Default Value | 0x300 + Node-ID |

|               |                   |
|---------------|-------------------|
| Sub Index     | 2                 |
| Description   | Transmission Type |
| Data Type     | Unsigned8         |
| Access        | rw                |
| PDO Mapping   | No                |
| Default Value | 253               |

**Object 0x1402: 3rd Receive PDO Communication Parameter**

## Manufacturer PDO Transmission Mode

The **ServoPac TT** drive has a special transmission mode for the TPDOOn defined by a TPDOOn\_Control (object 0x23A1-n) and a TPDO\_Count (object 0x23A0). The purpose of this mode is to control the number of cyclic TPDOOn for each axis.

TPDOOn\_Control is preset for each axis. TPDO\_Count is counter value of the host. For each axis, when TPDO\_Count is equal to TPDOOn\_Control, it will transmit the TPDOOn in synchronisation with the SYNC message. The transmission type for the TPDOOn must be 254.

Example: RPDO1 is used to transmit TPDO\_Count value.

To be sure that all axes have got the same value of TPDO\_Count at the same synchronisation, the RPDO1 COB-ID must be re-defined to be the same for all axes and mapped with TPDO\_Count object.

### 3.1.1.6 - Service Data Objects (SDO)

The SDO is a communication channel with 2 basic characteristics:

- Client/Server relationship,
- Object Dictionary.

#### Client/Server:

This is a relationship between a single client and a single server (Servo Drive). A client issues a request (upload/download) thus triggering the server to perform a certain task. After finishing the task, the server answers the request.

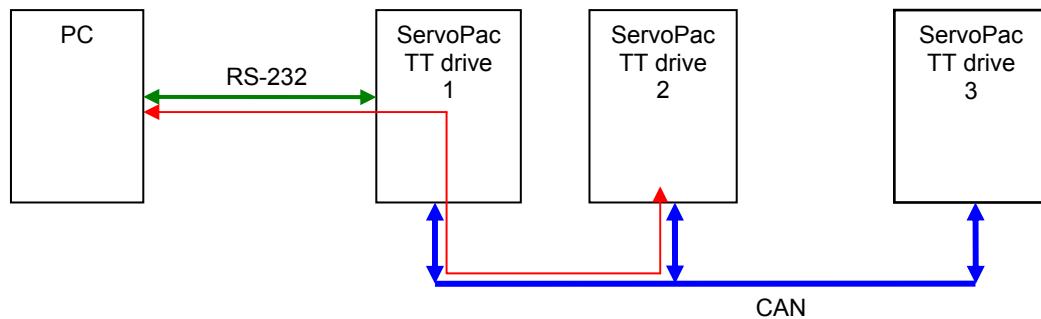

#### Object Dictionary:

All objects (variables, constants, records...) of the server are defined as a list of objects where each element is appointed by an index and a sub-index. This object list is called object dictionary. This object dictionary allows the client accessing all objects of the server. The Servo Drive object dictionary consists of 2 parts: the communication profile (DS-301) for the objects related to the CAN communication and the device profile (DSP-402) for objects related to the drive functionality.

For more information about the SDO protocol, please report to the CiA DS-301 version 4.01 specification.

### SDO Communication between drives

The **ServoPac TT** drive supports Node ID setting by switches from 1 to 63.

SDO message for node ID from 64 to 127 are used for communication between drives.  
The **ServoPac TT** drive re-directs the SDO message from RS-232 to CANbus via the PC.

Example: 3 drives with Node ID 1, 2 and 3.

direct SDO messages: cobID = 0x601/0x581, 0x602/0x582 and 0x603/0x583  
re-direct SDO messages: cobID = 0x641/0x5C1, 0x642/0x5C2 and 0x643/0x5C3

This allows the PC communicating with any drive only via one RS-232 connection (example of the red line in the above diagram).

With a **ServoPac TT** drive with node ID = n, there must not be another device in the CANopen network with node ID = n+64, to avoid conflict with the re-direction SDO message of the **ServoPac TT** drive.

### 3.1.1.7 - Emergency Objects

| Byte    | 0                    | 1                             | 2                                 | 3 | 4 | 5 | 6 | 7 |
|---------|----------------------|-------------------------------|-----------------------------------|---|---|---|---|---|
| Content | Emergency Error Code | Error register (object 1001h) | Manufacturer Specific Error Field |   |   |   |   |   |
|         |                      | Error Code                    |                                   |   |   |   |   |   |

See object 0x3022 for the Error Code.

### EMCY message behaviour

| Index         | 0x205F                 |
|---------------|------------------------|
| Name          | EMCY message Behaviour |
| Object Code   | VAR                    |
| Data Type     | Unsigned16             |
| Object Class  | All                    |
| Access        | rw                     |
| PDO Mapping   | No                     |
| Default Value | 1                      |

This object defines the behaviour of the EMCY message.

| Value | Description                                                                                                                                                    |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | EMCY message will not be sent                                                                                                                                  |
| 1     | EMCY message will be sent when an error occurs                                                                                                                 |
| 2     | EMCY message will be sent when an error occurs or an error reset (error code = 0)<br>The last case is not applicable for EtherCAT® (EMCY with error code = 0). |

### 3.1.1.8 - Node Guarding

#### Network error behaviour

| Index         | 0x205E                  |
|---------------|-------------------------|
| Name          | Network Error Behaviour |
| Object Code   | VAR                     |
| Data Type     | Unsigned16              |
| Object Class  | all                     |
| Access        | rw                      |
| PDO Mapping   | No                      |
| Default Value | 0                       |

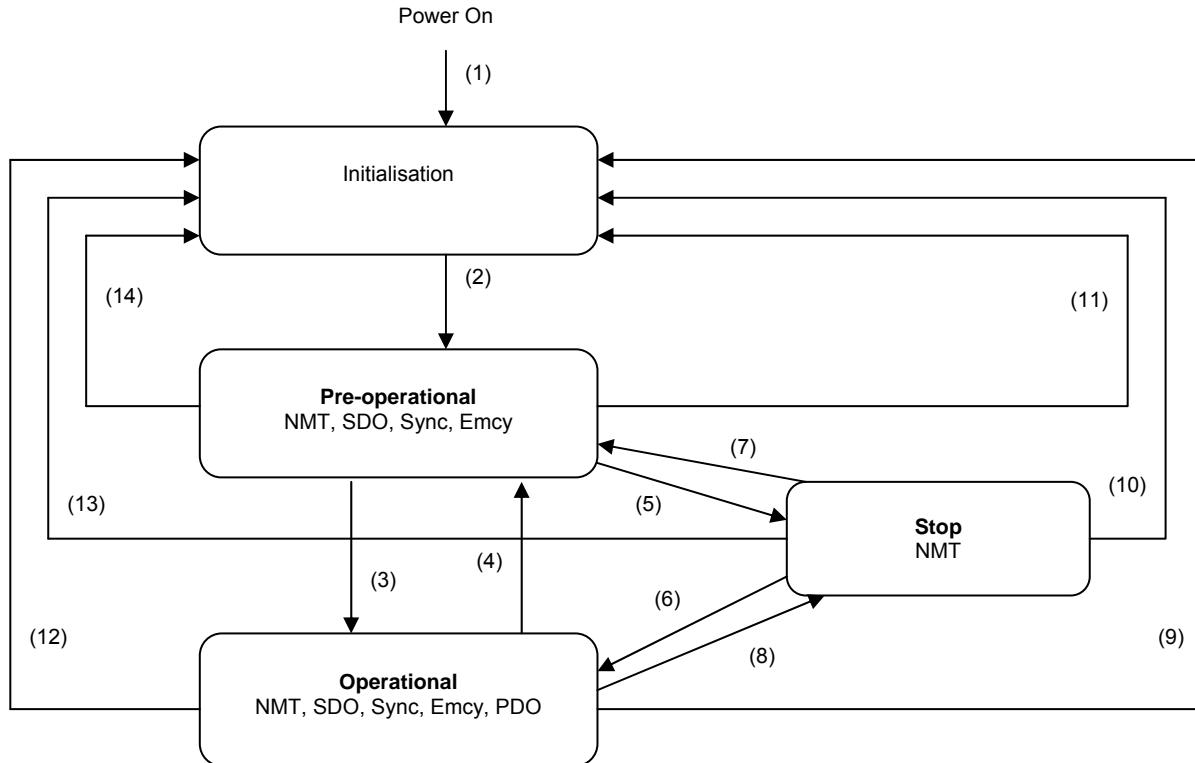

This object defines the drive behaviour when a Node guarding error occurs.

| Value | Description              |
|-------|--------------------------|
| 0     | No Operation             |
| 1     | Drive Error              |
| 2     | Goes into Bus Stop state |

### 3.1.2 - NETWORK INITIALISATION

#### 3.1.2.1 - NMT State Machine

The NMT state machine defines the communication status.

|                  |                                                                        |
|------------------|------------------------------------------------------------------------|
| (1)              | At Power on, the initialisation state is automatically entered         |
| (2)              | Once the Initialisation over, Pre-Operational is automatically entered |
| (3), (6)         | Start_Remote_Node indication                                           |
| (4), (7)         | Enter_Pre-Operational_State indication                                 |
| (5), (8)         | Stop_Remote_Node indication                                            |
| (9), (10), (11)  | Reset_Node indication                                                  |
| (12), (13), (14) | Reset_Communication indication                                         |

**Minimum Boot-Up** consists of one CAN telegram: a broadcast Start\_Remote\_Note message.

#### NMT reset

##### NMT\_Reset\_Comm:

The NMT\_Reset\_Comm restores communication parameters (default CobIDs, PDO mapping...) to the power-on values.

##### The NMT\_Reset\_Node:

Depending on object 0x205D, the NMT\_Reset\_Node can re-load the drive parameters file. An NMT\_Reset\_Comm is then executed.

## NMT reset configuration

|               |                         |
|---------------|-------------------------|
| <b>Index</b>  | <b>0x205D</b>           |
| Name          | NMT Reset configuration |
| Object Code   | VAR                     |
| Data Type     | Unsigned16              |
| Object Class  | all                     |
| Access        | rw                      |
| PDO Mapping   | No                      |
| Default Value | 0                       |

This object defines the reset behaviour of the drive.

| <b>Value</b> | <b>Description</b>                                                                                                |
|--------------|-------------------------------------------------------------------------------------------------------------------|
| 0            | Communication Reset only                                                                                          |
| 1            | Communication Reset and re-load drive parameters file<br>This operation can take some more time (several seconds) |
| 2            | Full drive reset (like when applying 24V)                                                                         |

## NMT Message: Start / Pre-Op Remote Nodes

|               |                           |
|---------------|---------------------------|
| <b>Index</b>  | <b>0x2000</b>             |
| Name          | Start/Pre-Op Remote Nodes |
| Object Code   | VAR                       |
| Data Type     | Unsigned16                |
| Object Class  | all                       |
| Access        | rw                        |
| PDO Mapping   | No                        |
| Default Value | 0                         |

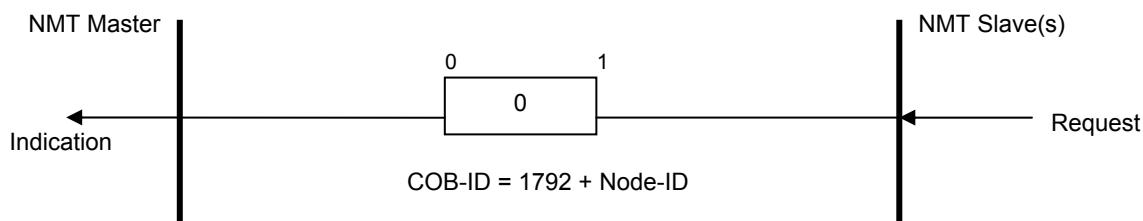

When writing to this object, an NMT message will be sent on the CAN bus. Depending on the written value, it allows starting or Pre-Op all nodes.

| <b>Value</b> | <b>Function</b>                                       |
|--------------|-------------------------------------------------------|
| 0            | Enter Pre-Op Remote Nodes                             |
| n            | Send a Start Nodes after n ms. Enter Operational mode |

### 3.1.2.2 - Bootup Protocol

This protocol is used to signal that a NMT slave has entered the node state PRE-OPERATIONAL after the state INITIALISING. The protocol uses the same identifier as the error control protocols.

#### Bootup Event

One data byte is transmitted with value 0.

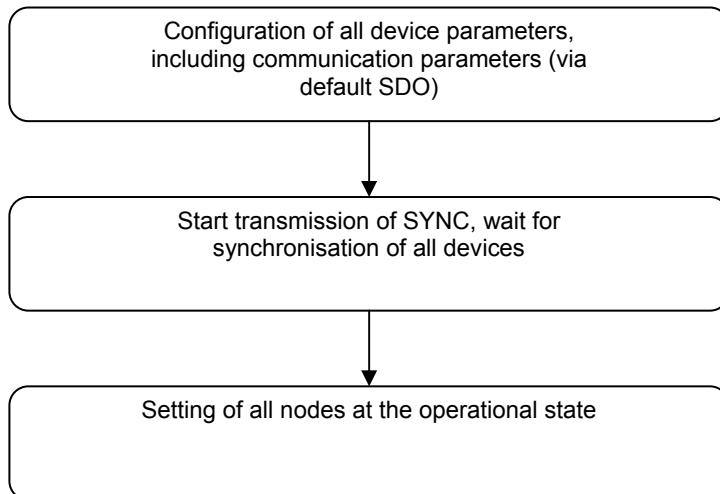

## CANopen Bootup configuration

|               |                              |
|---------------|------------------------------|
| <b>Index</b>  | <b>0x2010</b>                |
| Name          | CANopen Bootup configuration |
| Object Code   | VAR                          |
| Data Type     | Unsigned16                   |
| Object Class  | all                          |
| Access        | rw                           |
| PDO Mapping   | No                           |
| Default Value | 0                            |

This object defines the bootup behaviour of the drive.

| <b>Value</b> | <b>Description</b>                                           |
|--------------|--------------------------------------------------------------|
| 0            | No Bootup message                                            |
| 1            | Bootup message is sent when the drive goes into Pre-Op state |

### 3.1.2.3 - Initialisation procedure

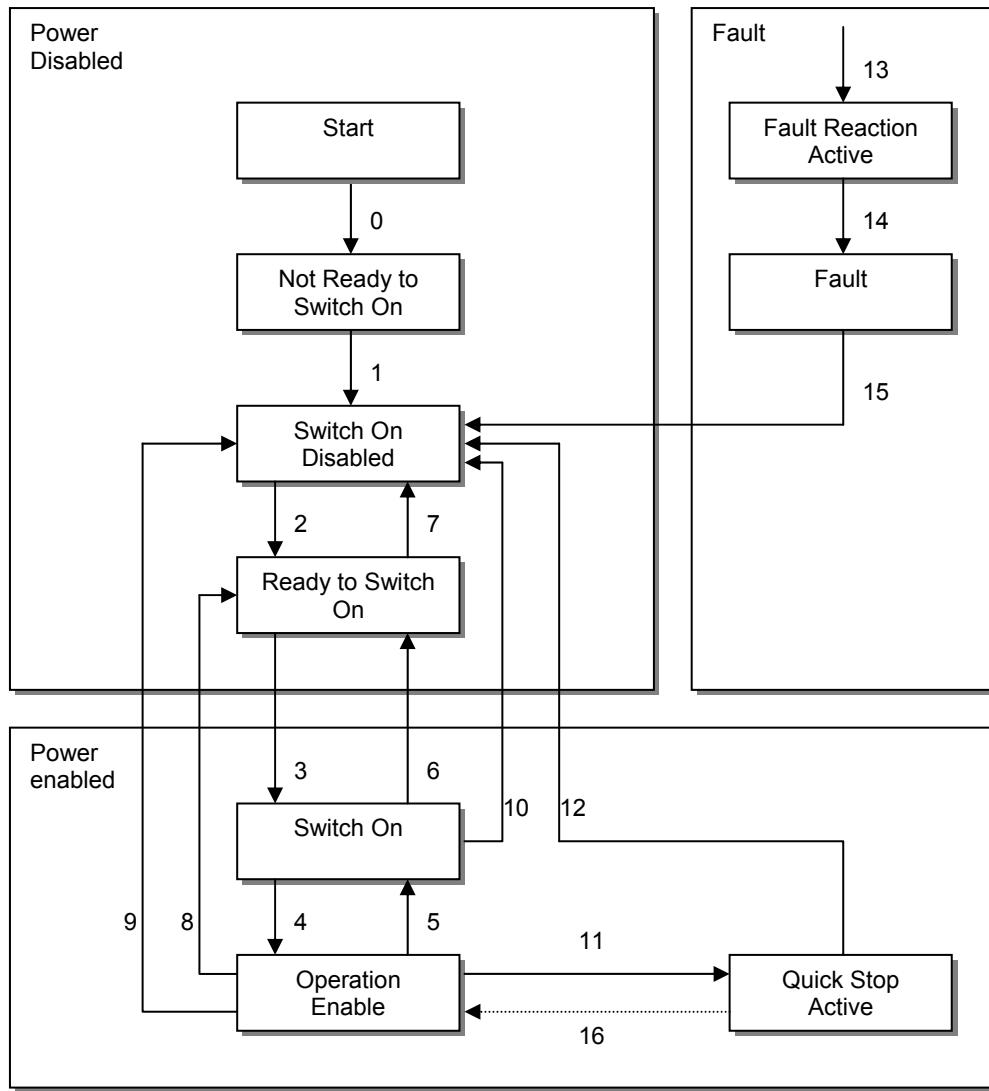

## 3.2 - DEVICE PROFILE

### 3.2.1 - DEVICE CONTROL

#### 3.2.1.1 - Drive State Machine

The state machine describes the status and the control sequence of the drive.

#### Drive State

The following states of the device are possible:

- NOT READY TO SWITCH ON

*Low level power has been applied to the drive.  
The drive is being initialized or is running self test.  
A brake, if present, has to be applied in this state.  
The drive function is disabled.*

- SWITCH ON DISABLED

*Drive initialization is complete.  
The drive parameters have been set up.  
Drive parameters may be changed.  
High voltage may not be applied to the drive, (e.g. for safety reasons).  
The drive function is disabled.*

- READY TO SWITCH ON

*High voltage may be applied to the drive.  
The drive parameters may be changed.  
The drive function is disabled.*

- SWITCHED ON

*High voltage has been applied to the drive.  
The power amplifier is ready.  
The drive parameters may be changed.  
The drive function is disabled.*

- OPERATION ENABLE

*No faults have been detected.  
The drive function is enabled and power is applied to the motor.  
The drive parameters may be changed.  
(This corresponds to normal operation of the drive.)*

- QUICK STOP ACTIVE

*The drive parameters may be changed.  
The quick stop function is being executed.  
The drive function is enabled and power is applied to the motor.*

- FAULT REACTION ACTIVE

*The drive parameters may be changed.  
A fault has occurred in the drive.  
The quick stop function is being executed.  
The drive function is enabled and power is applied to the motor.*

- FAULT

*The drive parameters may be changed.  
A fault has occurred in the drive.  
High voltage switch-on/-off depends on the application.  
The drive function is disabled.*

## State Transitions

State transitions are caused by internal events in the drive or by commands from the host via the control word.

- State Transition 0: START -> NOT READY TO SWITCH ON

*Event: Reset.*

*Action: The drive self-tests and/or self-initializes.*

- State Transition 1: NOT READY TO SWITCH ON -> SWITCH ON DISABLED

*Event: The drive has self-tested and/or initialized successfully.*

*Action: Activate communication.*

- State Transition 2: SWITCH ON DISABLED -> READY TO SWITCH ON

*Event: 'Shutdown' command received from host.*

*Action: None*

- State Transition 3: READY TO SWITCH ON -> SWITCHED ON

*Event: 'Switch On' command received from host.*

*Action: The power section is switched on if not already on.*

- State Transition 4: SWITCHED ON -> OPERATION ENABLE

*Event: 'Enable Operation' command received from host.*

*Action: The drive function is enabled.*

- State Transition 5: OPERATION ENABLE -> SWITCHED ON

*Event: 'Disable Operation' command received from host.*

*Action: The drive operation will be disabled.*

- State Transition 6: SWITCHED ON -> READY TO SWITCH ON

*Event: 'Shutdown' command received from host.*

*Action: The power section is switched off.*

- State Transition 7: READY TO SWITCH ON -> SWITCH ON DISABLED  
*Event: 'Quick Stop' and 'Disable Voltage' command received from host.*  
*Action: None*
- State Transition 8: OPERATION ENABLE -> READY TO SWITCH ON  
*Event: 'Shutdown' command received from host.*  
*Action: The power section is switched off immediately, and the motor is free to rotate if unbraked.*
- State Transition 9: OPERATION ENABLE -> SWITCH ON DISABLED  
*Event: 'Disable Voltage' command received from host.*  
*Action: The power section is switched off immediately, and the motor is free to rotate if unbraked.*
- State Transition 10: SWITCHED ON -> SWITCH ON DISABLED  
*Event: 'Disable Voltage' or 'Quick Stop' command received from host.*  
*Action: The power section is switched off immediately, and the motor is free to rotate if unbraked.*
- State Transition 11: OPERATION ENABLE -> QUICK STOP ACTIVE  
*Event: 'Quick Stop' command received from host.*  
*Action: The quick stop function is executed.*
- State Transition 12: QUICK STOP ACTIVE -> SWITCH ON DISABLED  
*Event: 'Quick Stop' is completed or 'Disable Voltage' command received from host.*  
*This transition is possible, if the Quick-Stop-Option-Code is different from 5 (stay in the state 'Quick Stop Active').*  
*Action: The power section is switched off.*
- State Transition 13: All states -> FAULT REACTION ACTIVE  
*A fault has occurred in the drive.*  
*Action: Execute appropriate fault reaction.*
- State Transition 14: FAULT REACTION ACTIVE -> FAULT  
*Event: The fault reaction is completed.*  
*Action: The drive function is disabled. The power section may be switched off.*
- State Transition 15: FAULT -> SWITCH ON DISABLED  
*Event: 'Fault Reset' command received from host.*  
*Action: A reset of the fault condition is carried out if no fault currently exists in the drive.*  
*After leaving the state Fault the Bit 'Fault Reset' of the control word has to be cleared by the host.*
- State Transition 16: QUICK STOP ACTIVE -> OPERATION ENABLE  
*Event: 'Enable Operation' command received from host. This transition is possible if the Quick-Stop-Option-Code is 5, 6, 7 or 8.*  
*Action: The drive function is enabled.*

### Objects definition

| 1          | Disable Voltage            |
| 2          | Quick Stop                 |
| 3          | Enable Operation           |
| 4          | Operation Mode Specific    |
| 5          | Operation Mode Specific    |
| 6          | Operation Mode Specific    |
| 7          | Reset Fault (rising edge)  |
| 8          | Halt (mode PV, PT, AS, AT) |

Device control commands are triggered by the following bit patterns in the control word:

| Command / Bit of the control_word | bit 7<br>Fault Reset | bit 3<br>Enable<br>Operation | bit 2<br>Quick Stop | bit 1<br>Disable<br>Voltage | bit 0<br>Switch On | Transition   |
|-----------------------------------|----------------------|------------------------------|---------------------|-----------------------------|--------------------|--------------|
| Shutdown                          | X                    | X                            | 1                   | 1                           | 0                  | 2, 6, 8      |
| Switch On                         | X                    | X                            | 1                   | 1                           | 1                  | 3            |
| Disable Voltage                   | X                    | X                            | X                   | 0                           | X                  | 7, 9, 10, 12 |
| Quick Stop                        | X                    | X                            | 0                   | 1                           | X                  | 7, 10, 11    |
| Disable Operation                 | X                    | 0                            | 1                   | 1                           | 1                  | 5            |
| Enable Operation                  | X                    | 1                            | 1                   | 1                           | 1                  | 4, 16        |
| Fault Reset                       | ↑                    | X                            | X                   | X                           | X                  | 15           |

Bit 4, 5, 6 are operation mode specific:

| Mode                       | Bit 4                  | Bit 5                  | Bit6                       |
|----------------------------|------------------------|------------------------|----------------------------|
| Profile Position Mode      | new set point          | change_set_immediately | 0: absolute<br>1: relative |
| Homing Mode                | Homing Operation Start | reserved               | reserved                   |
| Interpolated Position Mode | enable_ip_mode         | reserved               | reserved                   |
| Profile Velocity Mode      | reserved               | reserved               | reserved                   |

Correct sequence to enable the drive:

| Seq | Control Word (0x6040) | Corresponding Status Word (0x6041) | Remarks                                         |
|-----|-----------------------|------------------------------------|-------------------------------------------------|
| 1   | 0x0000                | 0x0240                             | state "Switch On Disabled"<br>drive is disabled |
| 2   | 0x0006                | 0x0221                             | state "Ready To Switch On"<br>drive is disabled |
| 3   | 0x0007                | 0x0223                             | state "Switch On"<br>drive is enabled           |
| 4   | 0x000F                | 0x0227                             | state "Operation Enable"<br>drive is enabled    |

#### Notes:

- Some independent status bits may be set and are not represented in the table above. The mask for testing the status word is 0x026F.
- Seq 1 (control word = 0x0000) and seq 3 (control word = 0x0007) may be omitted.
- In some operation modes (interpolated position mode, servo mode...), bit 4 of the control word must also be set after seq 4 to be fully operational. When switching between the modes, it is necessary to reset bit 4 of control word before changing the mode and then set it afterwards.

## Status Word

| Index         | 0x6041      |
|---------------|-------------|
| Name          | Status Word |
| Object Code   | VAR         |
| Data Type     | Unsigned16  |
| Object Class  | all         |
| Access        | ro          |
| PDO Mapping   | Possible    |
| Default Value | -           |

The status word indicates the current status of the drive. It is possible to define the TPDO to be transmitted at every change of the status word (Device Event transmission type).

| Bit Number | Function                                                     |
|------------|--------------------------------------------------------------|
| 0          | Ready to Switch On                                           |
| 1          | Switch On                                                    |
| 2          | Operation Enabled                                            |
| 3          | Fault                                                        |
| 4          | Voltage Enabled                                              |
| 5          | Quick Stop                                                   |
| 6          | Switch On Disabled                                           |
| 7          | Warning                                                      |
| 8          | Manufacturer Specific: user programmable (see object 0x3044) |
| 9          | Remote                                                       |
| 10         | Target Reached                                               |
| 11         |                                                              |
| 12         | Operation Mode Specific                                      |
| 13         | Operation Mode Specific                                      |
| 14         | Manufacturer Specific: user programmable (see object 0x3044) |
| 15         | Manufacturer Specific: Drive Busy                            |

Device Status Bit Meaning:

| State                  | Bit 6<br>Switch On<br>Disable | Bit 5<br>Quick Stop | Bit 3<br>Fault | Bit 2<br>Operation<br>Enable | Bit 1<br>Switched<br>On | Bit 0<br>Ready to<br>Switch On |
|------------------------|-------------------------------|---------------------|----------------|------------------------------|-------------------------|--------------------------------|
| Not Ready to Switch On | 0                             | X                   | 0              | 0                            | 0                       | 0                              |
| Switch On Disabled     | 1                             | X                   | 0              | 0                            | 0                       | 0                              |
| Ready to Switch On     | 0                             | 1                   | 0              | 0                            | 0                       | 1                              |
| Switched On            | 0                             | 1                   | 0              | 0                            | 1                       | 1                              |
| Operation Enable       | 0                             | 1                   | 0              | 1                            | 1                       | 1                              |
| Fault                  | 0                             | X                   | 1              | 0                            | 0                       | 0                              |
| Fault Reaction Active  | 0                             | X                   | 1              | 1                            | 1                       | 1                              |
| Quick Stop Active      | 0                             | 0                   | 0              | 1                            | 1                       | 1                              |

Bits 12, 13 are operation mode specific:

| Mode                       | Bit 12               | Bit 13          |  |
|----------------------------|----------------------|-----------------|--|
| Profile Position Mode      | setpoint acknowledge | Following Error |  |
| Homing Mode                | Homing attained      | Homing error    |  |
| Interpolated Position Mode | Ip-Mode active       | reserved        |  |
| Profile Velocity Mode      | Speed = 0            | reserved        |  |

## Status word manufacturer bits configuration

|                    |                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>       | <b>0x3044</b>                                                                                                                                         |
| Name               | Status word manufacturer bits configuration<br>Bits 8 and 14 of status word (0x6041,0) can be used to give the state of any bit from a source signal. |
| Object Code        | ARRAY                                                                                                                                                 |
| Number of Elements | 2                                                                                                                                                     |

### Value Description

|               |                                             |
|---------------|---------------------------------------------|
| Sub Index     | 1                                           |
| Description   | Source signal link for bit 8 in status word |
| Data Type     | Unsigned32                                  |
| Object Class  | All                                         |
| Access        | rw                                          |
| PDO Mapping   | No                                          |
| Default Value | 0x00000000                                  |

The structure of the source signal entries is the following:

|                |                   |                     |
|----------------|-------------------|---------------------|
| MSB            |                   | LSB                 |
| Index (16-bit) | Sub-index (8-bit) | Bit number n (0-31) |

The state of bit n of the variable defined by its index and sub-index will be copied into bit 8 of the status.  
The index/sub-index must correspond to an object type = variable (can be mapped in a TPDO).

|               |                                              |
|---------------|----------------------------------------------|
| Sub Index     | 2                                            |
| Description   | Source signal link for bit 14 in status word |
| Data Type     | Unsigned32                                   |
| Object Class  | All                                          |
| Access        | Rw                                           |
| PDO Mapping   | No                                           |
| Default Value | 0x00000000                                   |

The structure of the source signal entries is the following:

|                |                   |                     |
|----------------|-------------------|---------------------|
| MSB            |                   | LSB                 |
| Index (16-bit) | Sub-index (8-bit) | Bit number n (0-31) |

The state of bit n of the variable defined by its index and sub-index will be copied into bit 14 of the status word.  
The index/sub-index must correspond to an object type = variable (can be mapped in a TPDO).

#### Example:

Copy logic input IN1 to bit 8 of the status word:  
0x3044,1 = 0x60FD0010

Copy the home switch input to bit 14 of the status word  
0x3044,2 = 0x60FD0002

## Control word manufacturer bits configuration

| Sub Index     | 1                                             |
| Description   | Target signal link for bit 11 of control word |
| Data Type     | Unsigned32                                    |
| Object Class  | All                                           |
| Access        | Rw                                            |
| PDO Mapping   | No                                            |
| Default Value | 0x00000000                                    |

The structure of the target signal entries is the following:

| MSB            | LSB                                   |
|----------------|---------------------------------------|
| Index (16-bit) | Sub-index (8-bit) Bit number n (0-31) |

The state of bit 11 of the control word will be copied the bit n of the variable defined by its index and sub-index.  
The index/sub-index must correspond to an object type = variable (can be mapped in a RPDO).

|               |                                               |
|---------------|-----------------------------------------------|
| Sub Index     | 2                                             |
| Description   | Target signal link for bit 12 of control word |
| Data Type     | Unsigned32                                    |
| Object Class  | All                                           |
| Access        | Rw                                            |
| PDO Mapping   | No                                            |
| Default Value | 0x00000000                                    |

The structure of the target signal entries is the following:

| MSB            | LSB                                   |
|----------------|---------------------------------------|
| Index (16-bit) | Sub-index (8-bit) Bit number n (0-31) |

The state of bit 12 of the control word will be copied into bit n of the variable defined by its index and sub-index.  
The index/sub-index must correspond to an object type = variable (can be mapped in a RPDO).

#### Example:

Copy bit 11 of control word to logic output OUT2:  
0x3045,1 = 0x60FE0111

## Device Control

| Index         | 0x3440         |
|---------------|----------------|
| Name          | Device Control |
| Object Code   | VAR            |
| Data Type     | Unsigned16     |
| Object Class  | all            |
| Access        | rw             |
| PDO Mapping   | Possible       |
| Default Value | 0000           |

The device control allows activating drive specific functions.

| Bit Number | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| 0          | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 1          | Soft-Start activation:<br>This bit activation manually enables the soft start system at the drive power supply switch-on. It is used when the power supply switch-off duration is shorter than the DC bus voltage decreasing time below the “Undervoltage threshold” value. In this case, the manual soft start activation allows limiting the drive inrush current that can damage the mains circuit breaker (external to the drive).<br>When the DC bus voltage decreases below the “Undervoltage threshold” value, the soft start system is automatically activated. So, the manual activation is not required. |
| Others     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Device Status

| Index         | 0x3441        |
|---------------|---------------|
| Name          | Device Status |
| Object Code   | VAR           |
| Data Type     | Unsigned16    |
| Object Class  | all           |
| Access        | ro            |
| PDO Mapping   | Possible      |
| Default Value | -             |

The device status indicates the current status of drive specific functions.

| Bit Number | Function                                                                                                                                                   |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|

## In position signal configuration

| Index         | 0x306B                   |
|---------------|--------------------------|
| Description   | In position signal delay |
| Object Code   | VAR                      |
| Data Type     | Unsigned16               |
| Object Class  | pp ip hm eg              |
| Access        | rw                       |
| Unit          | ms                       |
| PDO Mapping   | No                       |
| Default Value | 0                        |

| Index         | 0x306E                       |
|---------------|------------------------------|
| Description   | In position signal threshold |
| Object Code   | VAR                          |
| Data Type     | Unsigned16                   |
| Object Class  | pp ip hm eg                  |
| Access        | rw                           |
| Unit          | User position unit /s        |
| PDO Mapping   | No                           |
| Default Value | 0                            |

When the position set point changing is lower than the threshold value, and the delay value is over, bit 8 of the device status (0x3441,0) is set.

### **3.2.1.2 - Error & Warning**

#### **3.2.1.2.1 - Error**

##### **Error:**

Errors are displayed in object 0x3022,1 (32-bit) and 0x3022,2 (32-bit), each bit in this object corresponds to one error.

Error bit in status (bit 3) is set as well.

An emergency message is sent with the last error code (error code is error bit number+1).

The same bit in objects 0x3025,1 and 0x3025,2 allows the inhibition of the corresponding error in 0x3022,1 and 0x3022,2.

The same bit in objects 0x3025,3 and 0x3025,4 allows triggering a stop 2 when the corresponding error in 0x3022,1 and 0x3022,2 occurs.

The same bit in objects 0x3025,5 and 0x3025,6 allows triggering a stop 3 when the corresponding error in 0x3022,1 and 0x3022,2 occurs.

An error can be cleared by "Reset Fault" bit in control word (0x6040).

##### **Error control:**

Object 0x3025 allows:

- the inhibition of some errors
- or triggering a stop 2 or stop 3 when the corresponding error occurs.

| Index  | Object | Name          | Type | Attr. |

| Object Code        | ARRAY         |
| Number of Elements | 3             |

##### **Value Description**

This object contains two 32-bit words in which one bit is assigned to a different error.  
The Error code is the value which will be sent as an emergency message (EMCY).

### Error Control

| Index              | 0x3025        |
|--------------------|---------------|
| Name               | Error control |
| Object Code        | ARRAY         |
| Number of Elements | 6             |

### Value Description

|               |              |
|---------------|--------------|
| Sub Index     | 1            |
| Description   | Error mask 1 |
| Data Type     | Unsigned32   |
| Object Class  | all          |
| Access        | rw           |
| PDO Mapping   | No           |
| Value         | See 0x3022-1 |
| Default value | No           |

|               |              |
|---------------|--------------|
| Sub Index     | 2            |
| Description   | Error mask 2 |
| Data Type     | Unsigned32   |
| Object Class  | all          |
| Access        | rw           |
| PDO Mapping   | No           |
| Value         | See 0x3022-2 |
| Default value | No           |

These 2 elements (0x3025,1 and 0x3025,2) allow the inhibition of the corresponding error.

|               |                     |
|---------------|---------------------|
| Sub Index     | 3                   |
| Description   | Error Stop 2 mask 1 |
| Data Type     | Unsigned32          |
| Object Class  | all                 |
| Access        | rw                  |
| PDO Mapping   | No                  |
| Value         | See 0x3022-1        |
| Default value | No                  |

|               |                     |
|---------------|---------------------|
| Sub Index     | 4                   |
| Description   | Error Stop 2 mask 2 |
| Data Type     | Unsigned32          |
| Object Class  | all                 |
| Access        | rw                  |
| PDO Mapping   | No                  |
| Value         | See 0x3022-2        |
| Default value | No                  |

These 2 elements (0x3025,3 and 0x3025,4) allow triggering a stop 2 when the corresponding error occurs.

|               |                     |
|---------------|---------------------|
| Sub Index     | 5                   |

| PDO Mapping   | No                  |
| Value         | See 0x3022-2        |
| Default value | No                  |

These 2 elements (0x3025,5 and 0x3025,6) allow triggering a stop 3 when the corresponding error occurs.

### Stop On Error operation

Drive parameters 0x3025,3 and 0x3025,4 (Error Stop 2 mask) allow selecting a Stop 2 behaviour (Slow down ramp) for a given drive fault when this fault occurs.

Drive parameters 0x3025,5 and 0x3025,6 (Error Stop 3 mask) allow selecting a Stop 3 behaviour (Slow down in current limitation) for a given drive fault when this fault occurs.

On a given fault occurrence, if the corresponding bit is equal to 0 in both “Error Stop 1 mask” and “Error Stop 3 mask” parameters, a Stop 0 is executed (power stage switched off and motor brake activated). This is the default drive configuration for the Stop on error functionality.

The Stop 2 and Stop 3 selections are not compatible with any fault occurrence situation.

The conditions for a possible Stop 3 operation are listed below:

- motor power control is fully operating
- motor position feedback signal is not corrupted

The Stop 2 selection is more restrictive than Stop 3 because the slow down ramp requires a correct motion control chaining when the fault occurs. The conditions for a possible Stop 2 operation are listed below:

- motor power control is fully operating
- motor position feedback signal is not corrupted
- position and speed set point are not corrupted

The Stop 2 or Stop 3 selection requires a careful failure case analysis. The drive operating mode, the application context and the machine safety requirements must all be considered.

For example, in the Interpolated Position mode, if a communication error occurs, the drive internal position set point is corrupted and can cause a wrong slow down ramp chaining. This situation can result in an uncontrolled motor movement. But if the drive is operating in Sequence mode, the drive position set point is not concerned by the fieldbus communication and the Stop 1 selection is then possible.

If an exhaustive failure case analysis in the application context cannot be carried, Stop 0 must be selected.

#### CAUTION !

A wrong “Stop on error” selection can cause uncontrolled motor movements that can be dangerous for operator and machine. It is the user's responsibility to check that a Stop 0 or Stop 2 or Stop 3 selection is compatible with his application.

Most faults are not compatible with the Stop 3 or Stop 2 selections. The possible “Stop on error” selection regarding the drive faults are listed in the chart below. When Stop 2 and Stop 3 are both compatible, the Stop 3 selection must be preferred.

| Error Code | Protection                                           | Possible Stop on error selection | Remarks                                                       |
|------------|------------------------------------------------------|----------------------------------|---------------------------------------------------------------|
| 34         | Velocity following error                             | Stop 0 or Stop 2 or Stop 3       | Stop 2 selection requires a careful fault occurrence analysis |
| 35         | Position following error                             | Stop 0 or Stop 2 or Stop 3       | Stop 2 selection requires a careful fault occurrence analysis |
| 36         | Software position limit                              | Stop 0 or Stop 2 or Stop 3       | Stop 2 selection requires a careful fault occurrence analysis |
| 37         | Motor Temperature error                              | Stop 0 or Stop 2 or Stop 3       | Stop 2 selection requires a careful fault occurrence analysis |
| 38         | I <sup>2</sup> t error                               | Stop 0 or Stop 2 or Stop 3       | Stop 2 selection requires a careful fault occurrence analysis |
| 46         | Extension Error or Fieldbus watchdog error           | Stop 0 or Stop 2 or Stop 3       | Stop 2 selection requires a careful fault occurrence analysis |
| 49         | Fieldbus SYNC cycle error                            | Stop 0 or Stop 2 or Stop 3       | Stop 2 selection requires a careful fault occurrence analysis |
| 50         | Fieldbus IP reference underflow/overflow             | Stop 0 or Stop 2 or Stop 3       | Stop 2 selection requires a careful fault occurrence analysis |
| 51         | Fieldbus guarding error                              | Stop 0 or Stop 2 or Stop 3       | Stop 2 selection requires a careful fault occurrence analysis |
| 58         | CAN Extension Module communication lost or not found | Stop 0 or Stop 2 or Stop 3       | Stop 2 selection requires a careful fault occurrence analysis |
| Other      |                                                      | Stop 0 only                      |                                                               |

**Important note:** When a Stop 2 or Stop 3 is executed due to a fault occurrence, a second fault occurrence with Stop 2 or Stop 3 selection cannot be considered.

### 3.2.1.2.2 - Warning

**Warning:**

Warning is displayed in object 0x3024,0 (32-bit).

Warning bit in status (bit 7) is also set.

Warning cannot be cleared by the user, it will automatically be cleared when the origin of the warning is discarded.

**Warning Code**

| Index         | 0x3024       |

| Default Value | No                      |

The motor RMS current value in Amps is calculated according to the following formula:  
RMS motor current (A) = Amplifier current rating (A) x [value(0x3404-2) x 5000 / 16384]<sup>1/2</sup> / 100

|               |                                       |

| Sub Index     | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Name          | Braking system operation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Description   | <b>The braking system operation is selected according to the drive configuration on the X9 connector.</b><br><b>- When the External resistor operation is selected, the duty cycle value is limited at 70 per thousand. This means a maximum braking transistor conduction of 70 ms over a period of 1 second.</b><br><b>- When the Internal resistor operation is selected, the duty cycle value is limited at 25 per thousand. This means a maximum braking transistor conduction of 25 ms over a period of 1 second. This selection allows protecting the drive internal 35 W braking resistor against overheating and failure.</b> |

| Description   | The braking resistor duty cycle limit parameter allows limiting the external braking resistor average power in order to protect it against overheating and failure. This parameter value is calculated according to the braking resistor specifications as described below:<br>Duty cycle limit = Braking resistor rated power (W) x Braking resistor ohmic value (Ohms) / Braking on threshold (V) / Braking on threshold (V) |

### 3.2.1.3 - Stop Operation

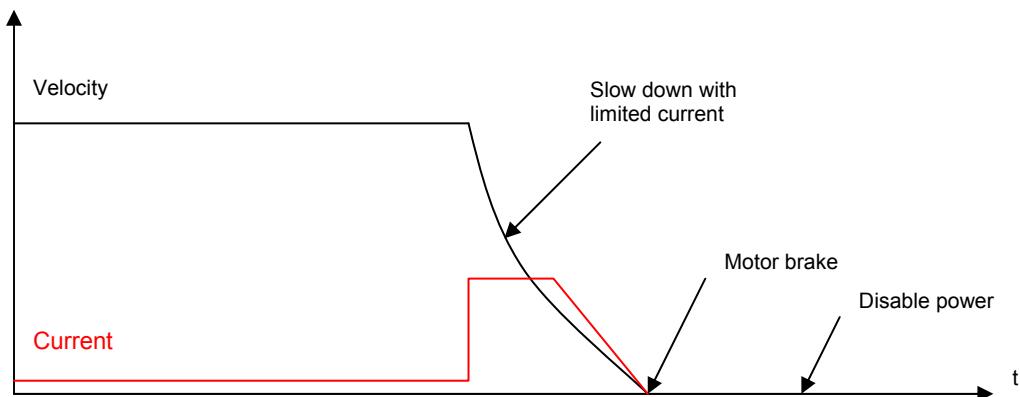

Stop 1 - stop on speed ramp: the motor is slowed down in position loop with a slow down ramp. The initial speed is defined with the reference speed.

Stop 2 - stop on speed ramp: the motor is slowed down in speed loop with a quick stop speed ramp. The initial speed is defined with the current motor speed.

Stop 3 - stop on current limit: the motor is slowed down in velocity loop with a current limitation.

| Stop option code | Action                                                        |
|------------------|---------------------------------------------------------------|
| 0                | Disable drive                                                 |
| 1                | Stopped on Slow down speed ramp and disabled                  |
| 2                | Stopped on Quick Stop speed ramp and disabled                 |
| 3                | Stopped on current limit and disabled                         |
| 5                | Stopped on Slow down speed ramp and stay in Quick Stop state  |
| 6                | Stopped on Quick Stop speed ramp and stay in Quick Stop state |
| 7                | Stopped on current limit and stay in Quick Stop state         |

When a transition of the state machine occurs, a stop can be performed. These transitions are:

- Quick Stop (transition 11)
- Disable Operation (transition 5)
- Shut down (transition 8)

Each transition can have different ways to stop, respectively defined in objects 0x605A, 0x605C and 0x605B.

The Inhibit input stops the drive with a parameter defined in object 0x305A.

Hardware limit switches stop with slow down speed ramp (with parameter in 0x3300,1)

Stop on current limit uses the current limit value defined in object 0x3301,1

Stop on slow down speed ramp uses the speed ramp defined in object 0x3300,1

Stop on quick stop speed ramp uses the speed ramp defined in object 0x6085,0

### Object definitions

| Index  | Object | Name                          | Type       | Attr. |
|--------|--------|-------------------------------|------------|-------|
| 0x605A | VAR    | Quick Stop Option Code        | Integer16  | rw    |
| 0x605B | VAR    | Shut down Option Code         | Integer16  | rw    |
| 0x605C | VAR    | Disable Operation Option Code | Integer16  | rw    |
| 0x305A | VAR    | Inhibit Option Code           | Integer16  | rw    |
| 0x3300 | ARRAY  | Slow down ramp                | Unsigned32 | rw    |
| 0x6085 | VAR    | Quick Stop ramp               | Unsigned32 | rw    |
| 0x3301 | ARRAY  | Stop Current Limit            | Integer16  | rw    |
| 0x3302 | ARRAY  | Stop Time Limit               | Unsigned16 | rw    |
| 0x3304 | VAR    | Amplifier Reaction Time       | Unsigned16 | rw    |
| 0x3305 | VAR    | Motor Brake Reaction Time     | Unsigned16 | rw    |

### Quick Stop Option Code

| Index         | 0x605A                 |
|---------------|------------------------|
| Name          | Quick Stop Option Code |
| Object Code   | VAR                    |
| Data Type     | integer16              |
| Object Class  | all                    |
| Access        | rw                     |
| PDO Mapping   | No                     |
| Default Value | 1                      |

This object defines the stop behaviour when a QUICK\_STOP command is executed (see Drive State Machine transition 11).

| <b>Quick stop option code</b> | <b>Action</b>                                                      |
|-------------------------------|--------------------------------------------------------------------|
| 0                             | Disable drive                                                      |
| 1                             | Stopped on Slow down speed ramp and disabled                       |
| 2                             | Stopped on Quick Stop speed ramp and disabled                      |
| 3                             | Stopped on current limit and disabled                              |
| 5                             | Stopped on Slow down speed ramp and stay in Quick Stop state       |
| 6                             | Stopped on Quick Stop speed ramp and stay in Quick Stop state      |
| 7                             | Stopped on current limit and disabled and stay in Quick Stop state |

### Shut Down Option Code

| <b>Index</b>  | <b>0x605B</b>         |
|---------------|-----------------------|
| Name          | Shut Down Option Code |
| Object Code   | VAR                   |
| Data Type     | integer16             |
| Object Class  | all                   |
| Access        | rw                    |
| PDO Mapping   | No                    |
| Default Value | 0                     |

This object defines the stop behaviour when a SHUTDOWN command is executed (see Drive State Machine transition 8).

| <b>Shut down option code</b> | <b>Action</b>                    |
|------------------------------|----------------------------------|
| 0                            | Disable operation                |
| 1                            | Stopped on Slow down speed ramp  |
| 2                            | Stopped on Quick Stop speed ramp |
| 3                            | Stopped on current limit         |

### Disable Operation Option Code

| <b>Index</b>  | <b>0x605C</b>                 |
|---------------|-------------------------------|
| Name          | Disable Operation Option Code |
| Object Code   | VAR                           |
| Data Type     | integer16                     |
| Object Class  | all                           |
| Access        | rw                            |
| PDO Mapping   | No                            |
| Default Value | 1                             |

This object defines the stop behaviour when a DISABLE\_OPERATION command is executed (see Drive State Machine transition 5).

| <b>Disable operation option code</b> | <b>Action</b>                    |
|--------------------------------------|----------------------------------|
| 0                                    | Disable operation                |
| 1                                    | Stopped on Slow down speed ramp  |
| 2                                    | Stopped on Quick Stop speed ramp |
| 3                                    | Stopped on current limit         |

## Inhibit Option Code

|               |                     |
|---------------|---------------------|
| <b>Index</b>  | <b>0x305A</b>       |
| Name          | Inhibit Option Code |
| Object Code   | VAR                 |
| Data Type     | integer16           |
| Object Class  | all                 |
| Access        | rw                  |
| PDO Mapping   | No                  |
| Default Value | 1                   |

This object defines the stop behaviour when an Inhibit logic input is activated (see Digital Inputs 0x60FD).

| Inhibit option code | Action                                        |
|---------------------|-----------------------------------------------|
| 0                   | Disable drive                                 |
| 1                   | Stopped on Slow down speed ramp and disabled  |
| 2                   | Stopped on Quick Stop speed ramp and disabled |
| 3                   | Stopped on current limit and disabled         |

## Slow Down Ramp

|                    |                |
|--------------------|----------------|
| <b>Index</b>       | <b>0x3300</b>  |
| Name               | Slow Down Ramp |
| Object Code        | ARRAY          |
| Number of Elements | 2              |

These parameters define the slow down deceleration with a stop executed with stop option code = 1 or 5 (Stopped on Slow down ramp).

### Value Description

|               |                   |
|---------------|-------------------|
| Sub Index     | 1                 |
| Description   | Slow Down Ramp 1  |
| Data Type     | Unsigned32        |
| Object Class  | all               |
| Access        | rw                |
| PDO Mapping   | No                |
| Unit          | Acceleration unit |
| Default Value |                   |

|               |                                              |
|---------------|----------------------------------------------|
| Sub Index     | 2                                            |
| Description   | Slow Down Ramp 2<br>reserved for future use. |
| Data Type     | Unsigned32                                   |
| Object Class  | all                                          |
| Access        | rw                                           |
| PDO Mapping   | No                                           |
| Unit          | Acceleration unit                            |
| Default Value |                                              |

## Quick Stop Ramp

|               |                   |
|---------------|-------------------|
| <b>Index</b>  | <b>0x6085</b>     |
| Name          | Quick Stop Ramp   |
| Object Code   | VAR               |
| Data Type     | Unsigned32        |
| Object Class  | all               |
| Access        | rw                |
| PDO Mapping   | No                |
| Unit          | Acceleration unit |
| Default Value | 0x00200000        |

This object defines the deceleration for a quick stop with Quick Stop Option Code = 2 or 6 (Stopped on Quick Stop ramp).

## Stop Current Limit

|                    |                    |
|--------------------|--------------------|
| <b>Index</b>       | <b>0x3301</b>      |
| Name               | Stop Current Limit |
| Object Code        | ARRAY              |
| Number of Elements | 2                  |

### Value Description

|               |                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------|
| Sub Index     | 1                                                                                                           |
| Description   | Stop Current Limit 1<br>This parameter defines the current limit when a stop on current limit is performed. |
| Data Type     | Unsigned16                                                                                                  |
| Object Class  | all                                                                                                         |
| Access        | rw                                                                                                          |
| PDO Mapping   | No                                                                                                          |
| Unit          | per thousand of rated current                                                                               |
| Value Range   | 100..6000                                                                                                   |
| Default Value | 1000                                                                                                        |

This parameter is used with a Quick Stop with Quick Stop Option Code = 3 or 7 (Stopped on current). This parameter is also applied with a stop at limit switches.

|               |                               |
|---------------|-------------------------------|
| Sub Index     | 2                             |
| Description   | Stop Current Limit 2          |
| Data Type     | Unsigned16                    |
| Object Class  | all                           |
| Access        | rw                            |
| PDO Mapping   | No                            |
| Unit          | per thousand of rated current |
| Value Range   | 100..6000                     |
| Default Value | 1000                          |

This parameter is reserved for future use.

## Stop Time Limit

|                    |                 |
|--------------------|-----------------|
| <b>Index</b>       | <b>0x3302</b>   |
| Name               | Stop Time Limit |
| Object Code        | ARRAY           |
| Number of Elements | 2               |

These parameters define the time limit for a stop operation.

When a stop on current limit is executed, the end of the stop may not be correctly detected if the axis is oscillating. The time stop limit allows limiting the execution time of the stop operation.

### Value Description

|               |                                                                    |
|---------------|--------------------------------------------------------------------|
| Sub Index     | 1                                                                  |
| Description   | Stop Time Limit 1<br>Time limit for all stop operations with ramp. |
| Data Type     | Unsigned16                                                         |
| Object Class  | all                                                                |
| Access        | rw                                                                 |
| PDO Mapping   | No                                                                 |

| Value Range   | 0..65000                                                                    |
| Default Value | 1000                                                                        |

## 3.2.2 - DRIVE PARAMETERS

### 3.2.2.1 - Motor parameters

The motor parameters are stored in object 0x6410

These values are the parameters given in the motor manufacturer's catalogue.

The motor control parameters

- number of pole pairs (0x6410-14),
- motor phase (0x6410-15),
- motor offset (0x6410-16)

will be respectively copied in objects 0x3410-1, 0x3410-2 and 0x3410-3.

Object 0x3410 can be possibly modified and will be used for the motor control (i.e. if the resolver wiring or adjustment is not correct).

The auto-phasing procedure will calculate these parameters of object 0x3410.

The motor inductance parameter of the catalogue (0x6410-13) will be copied in object 0x340F-0 and will be used for calculating the current loop gains (0x60F6).

Object 0x340F-0 can be possibly modified before calculating the gains if inductances are serially mounted with the motor.

The Maximum Motor Speed (0x6410-7) parameter of the catalogue will clip the motor speed peaks in 0x6080.

| PDO Mapping | No                             |
| Value       | 0x5555 (240°)<br>0xAAAA (120°) |

|             |              |
|-------------|--------------|
| Sub Index   | 3            |
| Description | Motor Offset |
| Data Type   | Unsigned16   |
| Access      | rw           |
| PDO Mapping | No           |
| Value       |              |

#### Auto-phasing procedure

|              |                              |
|--------------|------------------------------|
| Index        | 0x3413                       |
| Name         | Start Auto-phasing procedure |
| Object Code  |                              |
| Data Type    | Unsigned32                   |
| Object Class | all                          |
| Access       | rw                           |
| PDO Mapping  | No                           |

In order to avoid running the auto-phasing procedure by mistake, the auto-phasing is only executed when a specific signature is written to this sub-index. The signature is 'apha'.

Signature = 0x61687061

Writing 0 to this object when auto-phasing is running will abort the procedure.

When reading, this object returns the operation status:

| Read Value | Meaning                    |
|------------|----------------------------|
| 0          | Procedure never executed   |
| 1          | Cannot execute             |
| 2          | Procedure running          |
| 3          | Procedure aborted by user  |
| 4          | Procedure stopped on error |
| >= 5       | Procedure performed        |

When running, the BUSY bit of status word (0x6041) is set.

The auto-phasing procedure calculates these parameters:

number of pole pairs 0x3410,1

motor phase 0x3410,2

motor offset 0x3410,3

| Access       | rw                            |
| PDO Mapping  | No                            |

In order to avoid running the motor phasing procedure by mistake, the motor phasing is only executed when a specific signature is written to this sub-index. The signature is 'mcal'.

Signature = 0x6C61636D

Writing 0 to this object when motor phasing is running will abort the procedure.

When reading, this object returns the operation status:

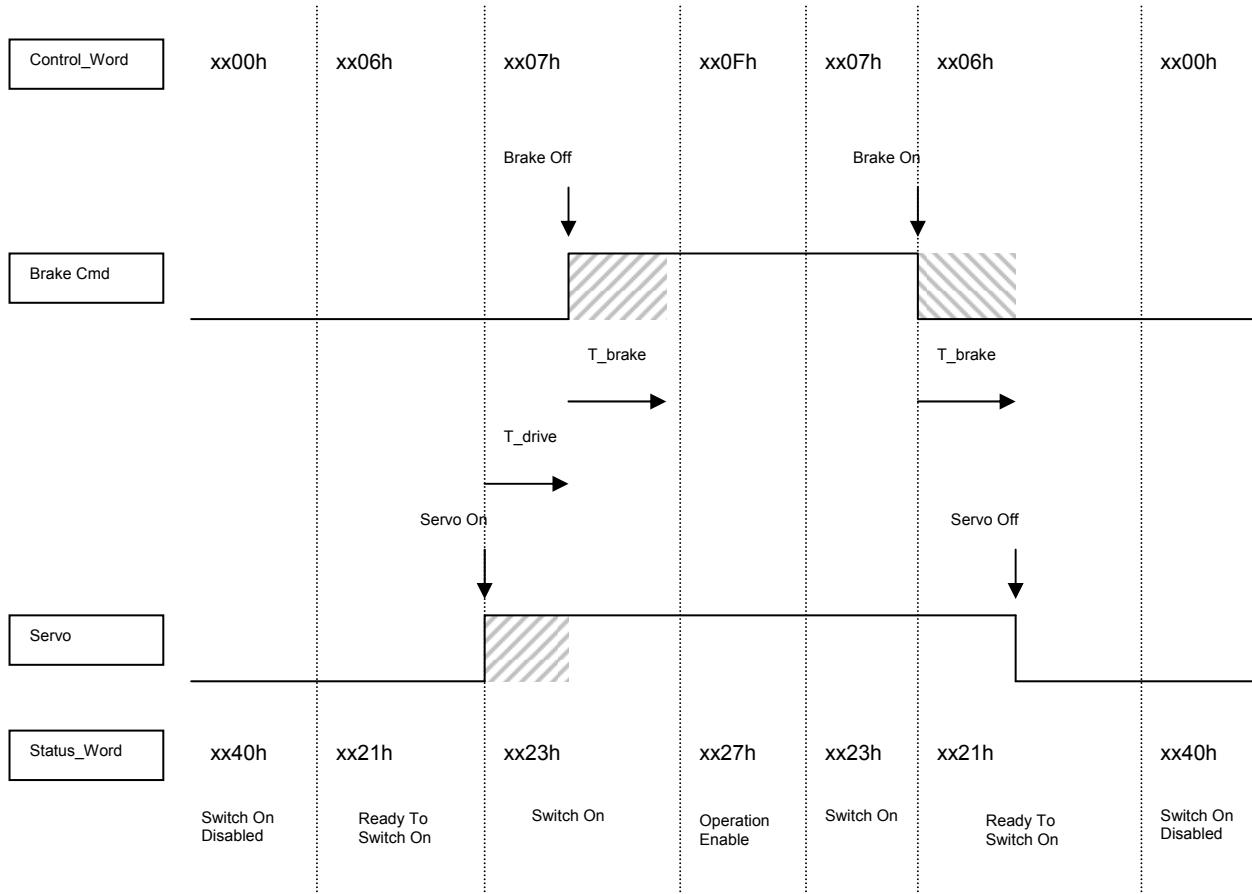

| Read Value | Meaning                    |
|------------|----------------------------|
| 0          | Procedure not executed     |
| 1          | Cannot execute             |
| 2          | Procedure running          |
| 3          | Procedure aborted by user  |
| 4          | Procedure stopped on error |
| >= 5       | Procedure performed        |

When running, the BUSY bit of status word (0x6041) is set.

The motor phasing procedure calculates these parameters: motor offset 0x3410,3

### 3.2.2.2 - Motor Brake

#### Servo On/Off Timing Diagram

| Index  | Object | Name                      | Type       | Attr. |
|--------|--------|---------------------------|------------|-------|
| 0x3304 | VAR    | Amplifier Reaction Time   | Unsigned16 | rw    |
| 0x3305 | VAR    | Motor Brake Reaction Time | Unsigned16 | rw    |

**Note:** The motor brake control is automatic with Switch On/Off by the control\_word. To disable the motor brake control, it is necessary to set at 1 bit 0 of object 60FE sub-index 2 (digital output bitmask). The motor brake is then manually controlled by bit 0 of object 60FE sub-index 1.

#### Drive Reaction Time

| Index         | 0x3304              |
|---------------|---------------------|
| Name          | Drive Reaction Time |
| Object Code   | VAR                 |
| Data Type     | Unsigned16          |
| Object Class  | all                 |
| Access        | rw                  |
| PDO Mapping   | No                  |
| Unit          | ms                  |
| Value Range   | 0..65535            |
| Default Value | x                   |

This parameter defines the reaction time of the drive when enabled / disabled.

## Motor Brake Reaction Time

|               |                           |
|---------------|---------------------------|
| <b>Index</b>  | <b>0x3305</b>             |
| Name          | Motor Brake Reaction Time |
| Object Code   | VAR                       |
| Data Type     | Unsigned16                |
| Object Class  | all                       |
| Access        | rw                        |
| PDO Mapping   | No                        |
| Unit          | ms                        |
| Value Range   | 0..65535                  |
| Default Value | 0                         |

This parameter defines the reaction time of the motor brake.

### 3.2.2.3 - Motor current limits & Current Loop

The parameters defining the current limitation to be applied to the motor are the following:

- Motor Max. Current 0x6073
- Motor Rated Current 0x6075

The motor parameters **Motor Peak Current** (0x6410-10) and **Motor stall Current** (0x6410-9) will be used for calculating the internal limitations of the drive according to the drive maximum and rated currents (0x6510). The values of the drive internal limitations can be displayed by object 0x30F4.

The current loop gains are accessible in object 0x60F6.

Object 0x3411 allows:

- calculating the current loop gains according to the motor parameters and the drive specifications:

Parameters:

Inductance (0x340F)  
Drive Max. current (0x6510-1)

Results:

Current Loop Gains (0x60F6)

Object 0x3412 allows:

- calculating the drive current limitations according to the motor and drive currents (0x6510):

Parameters:

Motor Peak current (0x6410-10)  
Motor Stall current (0x6410-9)  
Drive Max current (0x6510-1)  
Drive Rated current (0x6510-2)

Results:

Motor Max current (0x6073-0)  
Motor Rated current (0x6075-0)

The input parameters must be previously defined.

## Manufacturer Drive Data

|                    |                         |
|--------------------|-------------------------|
| <b>Index</b>       | <b>0x6510</b>           |
| Name               | Manufacturer Drive Data |
| Object Code        | ARRAY                   |
| Number of Elements | 5                       |

This object indicates the peak current and the rated current supported by the power module.

| PDO Mapping   | No                       |
| Default Value | 0                        |

When the motor inductance (0x6410) and drive current (0x6510) are correct, this object allows calculating the current loop parameters.

In order to avoid running this operation by mistake, the user must write a specific signature to this object to make the calculation.

The signature is 'calc'.

Signature = 0x636C6163

The parameters calculated are in object 0x60F6.

This procedure also calculates the current limit values (0x6073 and 0x6075)

| Data Type     | Unsigned32                                                                                                              |
| Object Class  | all                                                                                                                     |
| Access        | rw                                                                                                                      |
| Backup        | drive parameter file                                                                                                    |
| PDO Mapping   | No                                                                                                                      |
| Unit          | mV                                                                                                                      |
| Default Value | 0                                                                                                                       |
| Remark        | When this parameter value is 0, the “Undervoltage” bit is not controlled (reset to 0) in object 0X3024 (drive warning). |

When the DC bus voltage value drops below this parameter value, the “Undervoltage” bit is activated in object 0X3024 (drive warning).

### 3.2.2.4 - Dynamic current limits

The current applied to the motor is dynamically limited by the value of a defined object. By default, object 0x30D1 is used to limit the motor current (defined in 0x30DA).

The default value of object 0x30D1 is 0x3FFF and corresponds to the maximum current set by the user (0x6073).

#### Dynamic Current Limit Input Source

|               |                                    |
|---------------|------------------------------------|
| <b>Index</b>  | <b>0x30DA</b>                      |
| Name          | Dynamic Current Limit Input Source |
| Description   | Index/sub-index of input data      |
| Data Type     | Unsigned32                         |
| Object Class  | all                                |
| Access        | rw                                 |
| PDO Mapping   | No                                 |
| Default Value | 0x30D10000                         |
| Value         | See below                          |

This object allows connecting any dataflow as the source of the Dynamic Current Limit.

By default the object 0x30D1 is used as Dynamic Current Limit signal.

The structure of the entries is the following:

| MSB            | LSB                 |
|----------------|---------------------|
| Index (16-bit) | Sub-index (8-bit) 0 |

## Current Limit

| Sub Index     | 2                                   |
| Description   | Motor temperature warning threshold |
| Data Type     | Unsigned32                          |
| Access        | rw                                  |
| PDO Mapping   | No                                  |
| Unit          | $\Omega$ (ohm)                      |
| Default value | 2400                                |

This parameter defines the threshold of the equivalent resistor corresponding to the temperature at which a warning will be notified.

|               |                                   |

| PDO Mapping   | No                                |
| Unit          | $\Omega$ (ohm)                    |
| Default value | 2400                              |

This parameter defines the threshold of the equivalent resistor corresponding to the temperature at which an error will be triggered.

| Index        | 0x3323                             |
|--------------|------------------------------------|
| Name         | Motor temperature probe monitoring |
| Object Code  | VAR                                |
| Data Type    | Unsigned32                         |
| Object Class | all                                |
| Access       | ro                                 |
| Unit         | $\Omega$ (ohm)                     |
| PDO Mapping  | No                                 |

The returned value gives an image of the equivalent resistance (in  $\Omega$ ).

### 3.2.2.6 - IGBT temperature

IGBT module temperature value

| Index        | 0x3328                              |
|--------------|-------------------------------------|
| Name         | IGBT module temperature information |
| Object Code  | VAR                                 |
| Data Type    | Integer 16                          |
| Object Class | all                                 |
| Access       | ro                                  |
| PDO Mapping  | Yes                                 |
| Unit         | °C                                  |
| Remark       | Only valid for the 400 V range      |

### 3.2.2.7 - Sensors

The **ServoPac TT** servo drive has 2 sensor inputs: Resolver and Encoder

Each sensor can be used as motor feedback or position feedback.

| Index  | Object | Name                            | Type       | Attr. |
|--------|--------|---------------------------------|------------|-------|
| 0x306A | VAR    | Position Feedback Sensor Select | Unsigned16 | rw    |
| 0x3070 | VAR    | Motor Feedback Sensor Select    | Unsigned16 | rw    |

#### Position Feedback Sensor Select

| Index         | 0x306A                          |
|---------------|---------------------------------|
| Name          | Position Feedback Sensor Select |
| Object Code   | VAR                             |
| Data Type     | Unsigned16                      |
| Object Class  | all                             |
| Access        | rw                              |
| PDO Mapping   | No                              |
| Default Value | 0                               |

This object defines the feedback sensor which will be used to close the position loop.

| Value | Function          |
|-------|-------------------|
| 0     | Resolver Feedback |
| 1     | Encoder Feedback  |

When motor feedback and position feedback are different (resolver for motor feedback and encoder for position feedback, for example), both sensors must count in the same direction.

## Motor Feedback Sensor Select

| Index         | 0x3070                       |
|---------------|------------------------------|
| Name          | Motor Feedback Sensor Select |
| Object Code   | VAR                          |
| Data Type     | Unsigned16                   |
| Object Class  | all                          |
| Access        | rw                           |
| PDO Mapping   | No                           |
| Default Value | 0                            |

The motor feedback sensor is used to close the servo motor torque and speed control loops. The servo motor position loop can be closed by the motor feedback sensor or with the secondary sensor (see object 0x306A).

| Value | Function          |
|-------|-------------------|
| 0     | Resolver Feedback |
| 1     | Encoder Feedback  |

### 3.2.2.7.1 - Resolver

#### Resolver Parameters

| Name               | Resolver Setup |
| Object Code        | RECORD         |
| Number of Elements | 6              |

### Value Description

|               |               |
|---------------|---------------|
| Sub Index     | 1             |
| Description   | Resolver Type |
| Data Type     | Unsigned16    |
| Object Class  | all           |
| Access        | rw            |
| PDO Mapping   | No            |
| Default Value | 0             |

| Bit Number | Description             |
|------------|-------------------------|
| 0          | 1 Enabled<br>0 Disabled |
| 1, 2       | reserved                |
| 3          | 1 SinCos Track          |
| 4, 5       | reserved                |
| 6          | 1 Absolute Single-turn  |
| 7..15      | reserved                |

For a resolver, the setting value is 0x41

For a SinCos track encoder, the setting is 0x49

| Description   | Resolver Virtual Top Z shift |
| Data Type     | Unsigned16                   |
| Object Class  | all                          |
| Access        | rw                           |
| PDO Mapping   | No                           |
| Default Value | 0                            |

This parameter defines the offset between marker Z of the encoder and the virtual marker Z.

The value is given in encoder increments (4096 increments / revolution).

| Data Type     | Unsigned16                  |
| Object Class  | all                         |
| Access        | rw                          |
| PDO Mapping   | No                          |
| Default Value | 0                           |

This parameter defines the width of the virtual marker Z.  
The value is given in encoder increments (4096 increments / revolution).

The virtual marker Z is working with polling technique, the width of the virtual marker Z allows increasing the marker Z size in order to avoid a missing of the marker Z.

The status of the virtual marker Z can be read by object 0x3027

| Default Value | 0                                         |

See Resolver Position (0x3109).

### Resolver Position

| Index         | 0x3109                                    |
|---------------|-------------------------------------------|
| Name          | Resolver Position                         |
| Object Code   | VAR                                       |
| Data Type     | Integer32                                 |
| Object Class  | all                                       |
| Access        | ro                                        |
| PDO Mapping   | Yes                                       |
| Unit          | User Position Unit                        |
| Value Range   | (-2 <sup>31</sup> )..(2 <sup>31</sup> -1) |
| Default Value | -                                         |

This object monitors the resolver position:

$$\text{Resolver\_Position} = \text{Resolver\_Internal\_Position} + \text{Resolver\_Position\_Offset}$$

Resolver\_Position (0x3109) in user position unit is the position given by the resolver. If the position loop feedback is resolver, and the modulo function (Position Limit) is not activated, then the resolver position is the same as 0x6064.

Resolver\_Internal\_Position in user position unit is the resolver position value related to the initial position at power on.

Resolver\_Position\_Offset (0x3108) defines an offset between user position (0x3109) and internal resolver position. If the position loop feedback is resolver, this offset will be calculated by the homing procedure. At power on Resolver\_Position\_Offset is 0.

### **3.2.2.7.2 - Encoder**

Encoder support types:

- TTL Incremental Encoder
- TTL Incremental Encoder + Hall Effect Sensor
- Sin-Cos Incremental Encoder
- Sin-Cos Incremental Encoder + Hall Effect Sensor
- Hiperface® Encoder

| Description   | Encoder Virtual Top Z shift |
| Data Type     | Unsigned16                  |
| Object Class  | all                         |
| Access        | rw                          |
| PDO Mapping   | No                          |
| Default Value | 0                           |

This parameter defines the offset between marker Z of the encoder and the virtual marker Z.  
The value is given in encoder increments (encoder resolution x 4)

|               |                            |
|---------------|----------------------------|
| Sub Index     | 4                          |
| Description   | Encoder Virtual Top Z size |
| Data Type     | Unsigned16                 |
| Object Class  | all                        |
| Access        | rw                         |
| PDO Mapping   | No                         |
| Default Value | 0                          |

This parameter defines the width of the virtual marker Z.  
The value is given in encoder increments (encoder resolution x 4).

The virtual marker Z is working with polling technique, the width of the virtual marker Z allows increasing the marker Z size in order to avoid the missing of the marker Z.

The status of the virtual marker Z can be read by object 0x3127.

| Unit          | User Position Unit                        |
| Value Range   | (-2 <sup>31</sup> )..(2 <sup>31</sup> -1) |
| Default Value | 0                                         |

See Encoder Position (0x3129).

### Encoder Position

|               |                                           |
|---------------|-------------------------------------------|
| Index         | <b>0x3129</b>                             |
| Name          | Encoder Position                          |
| Object Code   | VAR                                       |
| Data Type     | Integer32                                 |
| Object Class  | all                                       |
| Access        | ro                                        |
| PDO Mapping   | Yes                                       |
| Unit          | User Position Unit                        |
| Value Range   | (-2 <sup>31</sup> )..(2 <sup>31</sup> -1) |
| Default Value | -                                         |

This object monitors the encoder position:

$$\text{Encoder\_Position} = \text{Encoder\_Internal\_Position} + \text{Encoder\_Position\_Offset}$$

Encoder \_Position (0x3129) in user position unit is the position given by the encoder. If the position loop feedback is encoder and modulo function (Position Limit) is not activated, then the encoder position is the same as 0x6064.

Encoder\_Internal\_Position in user position unit, is the encoder position value related to the initial position at power on.

Encoder\_Position\_Offset (0x3128) defines an offset between user position (0x3129) and internal encoder position. If the position loop feedback is encoder, this offset will be calculated by the homing procedure. At power on, Encoder\_Position\_Offset is 0.

If the encoder is absolute multi-turn, the Encoder\_Position\_Offset is saved in the drive parameter file, and is restored at power on.

### **3.2.2.7.3 - TTL Encoder**

An incremental TTL encoder can be connected to ServoPac TT drives as motor feedback or only as position feedback.

#### **Motor Feedback:**

Incremental TTL encoder is not absolute for motor commutation, so:

- In a first time, an auto-phasing must be performed to define the motor pole pair number, motor phase order, and encoder offset.
- Each time the drive is restarted with 24 V, a motor-phasing must be performed before the motor can be controlled.

#### Note:

- Motor-phasing applies torque and moves the motor
- Power supply must be on
- Please check that the motor is at standstill and its movement over one revolution dangerous neither for operator nor machine.
- Motor-phasing does not work with vertical axis or axis with driving load.

#### **Position Feedback:**

If the encoder is used as a position feedback only (motor feedback is resolver) then the encoder resolution defined in object 0x608F must be the encoder counts for one motor revolution.

### **3.2.2.7.4 - Sin-Cos Encoder**

An incremental SinCos encoder can be used with ServoPac TT drives as an incremental TTL encoder.

An internal SinCos interpolation allows the drive working at a higher resolution, which means better results on the speed loop.

### **3.2.2.7.5 - Hall Effect Sensor**

The Hall effect sensor can be used with a TTL incremental encoder or a Sin-Cos incremental encoder to avoid a motor phase search with motor-phasing operation each time the 24 V supply is applied.

The Hall effect sensor parameters are calculated with the auto-phasing procedure.

Parameters depending on the Hall effect sensor:

- Motor phase order: 0x3410,2
- Sensor offset: 0x3410,3
- Hall effect sensor parameter: 0x313E,0

| Index  | Object | Name              | Type       | Attr. |
|--------|--------|-------------------|------------|-------|

| Default Value | 0                         |

### Value Description

| Bit Number | Description                        |
|------------|------------------------------------|
| 0-2        | HES initial state                  |
| 3          | Direction                          |
| 4          | Type:<br>0      60°<br>1      120° |

#### Manual Configuration for an incremental encoder + HES:

0x3121,1 = 0x0013 ; incremental TTL encoder + HES

0x313E,0 = HES config

0x3410,1 = pole pairs

0x3410,2 = phase order

0x3410,3 = sensor offset (mechanic)

### **3.2.2.7.6 - Hiperface®**

A Hiperface® type encoder can be connected to a ServoPac TT drive.  
Only Hiperface® Encoder type different from 0xFF can be recognized.

#### **Setup Hiperface® encoder with Gem Drive Studio**

The Hiperface® Encoder commissioning can be done with Gem Drive Studio:

- Select Hiperface® Encoder
- Check "Enable encoder input"
- "Read Encoder Configuration" to read encoder parameters
- "Apply"

Move the motor by hand: if there is an "Encoder Commutation channel / Incremental channel Error", then toggle "Reverse Incremental Track".

#### **Setup Hiperface® encoder manually**

Enabling and selecting Hiperface® encoder are defined with object 0x3121,1.

Writing a 1 to object 0x312B,1 allows reading Hiperface® encoder parameters.

The Hiperface® encoder has an absolute information track (serial) and an incremental information track (Sin-Cos).

The two information tracks must evolve in the same direction. Inverting the Sin-Cos signals may change the counting direction of the Sin-Cos signal with regard to the absolute value from the serial channel.

If there is an "Encoder Commutation channel / Incremental channel Error" when moving the encoder (motor), then "Reverse Incremental track / Absolute track" bit in object 0x3121,1 must be toggled.

### **3.2.2.7.7 - Absolute Multi-turn Position**

With an absolute encoder feedback, the motor absolute position value over one revolution is available and the servo motor can immediately be enabled after the amplifier power up. The servo drive behaviour at power up is similar to a resolver sensor feedback. For a position application, an absolute multi-turn encoder allows avoiding the homing sequence after power up. In this case, the absolute position value over the axis travel distance is available at power up and the positioning can be immediately started. However, the axis must never leave the encoder absolute position range.

#### **Encoder Position Range**

The absolute encoder gives a position value between 0 and a maximum position value (depending on the encoder type).

For a Hiperface® encoder, the max. position value is given by:

(Number\_of\_revolutions x Number\_of\_periods x 4 x 8) - 1  
 Number\_of\_revolutions is the maximum revolution for that encoder.  
 Number\_of\_periods is the number of Sin-Cos periods per revolution  
 4 is the quadrature counter multiplier  
 8 is the interpolation factor.

Example 1:

Number\_of\_revolutions = 4096  
 Number\_of\_periods = 1024

Then, the maximum position value given by the encoder is  $4096 \times 1024 \times 4 \times 8 - 1 = 134\,217\,727 = 0x7FF\,FFF$

Once the encoder parameters set, this maximum position can be read with object 0x312D,1.

The current position of the encoder is given by object 0x312D,3

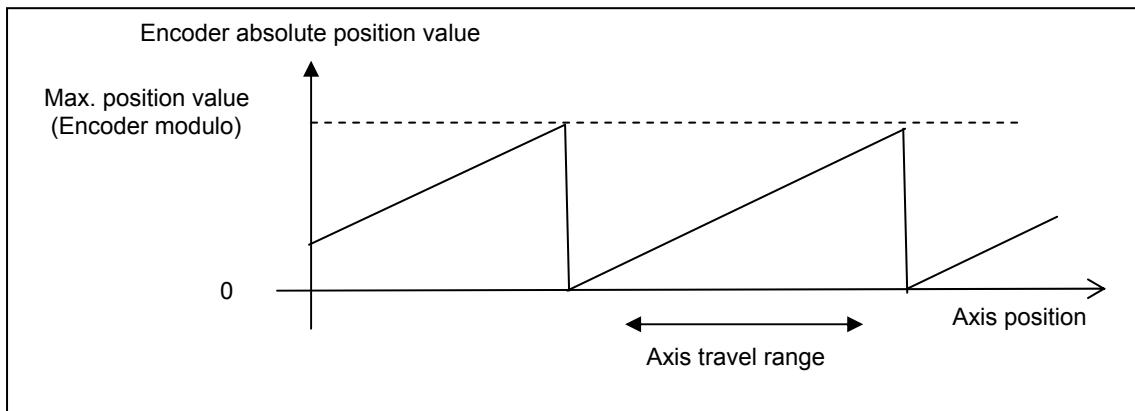

Note: these values are in encoder unit.

### Setting Motor Zero Position

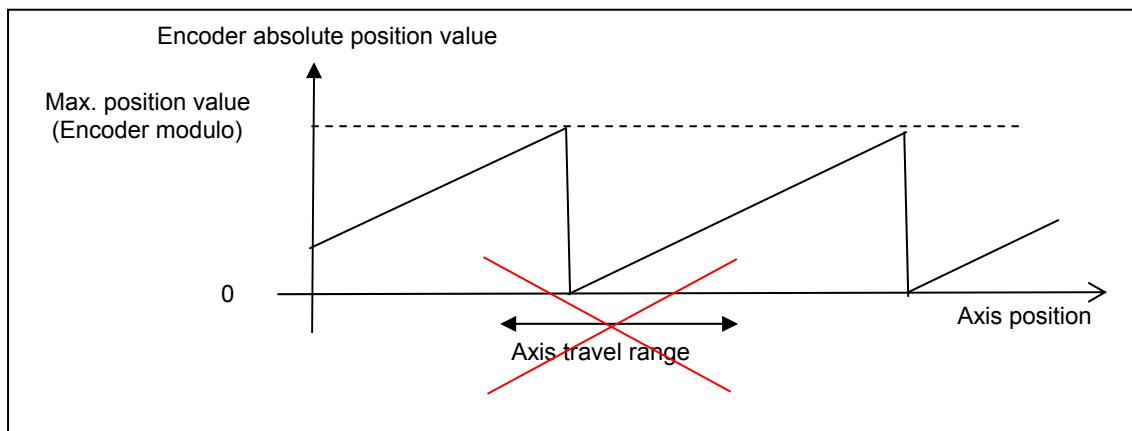

For the drive operation in absolute positioning mode (without a new homing sequence after each drive power up), proceed as described below.

- 1) Check that the encoder 0 position is outside the axis travel range by using the object 0x312D,3 (encoder position read)

An absolute encoder gives a position value between 0 and the maximum position value (encoder modulo). So, for an absolute positioning application, the encoder 0 position must be out of the axis travel range as shown below.

Correct encoder absolute position range adjustment

Wrong encoder absolute position range adjustment

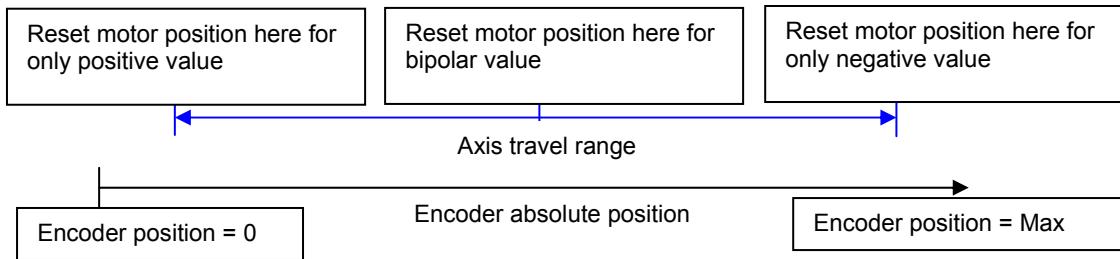

If the encoder 0 position is inside the axis travel range, uncouple the motor and adjust manually the encoder position range.

- 2) Adjust the motor position range by using the object 0x312B,1 (reset motor position)

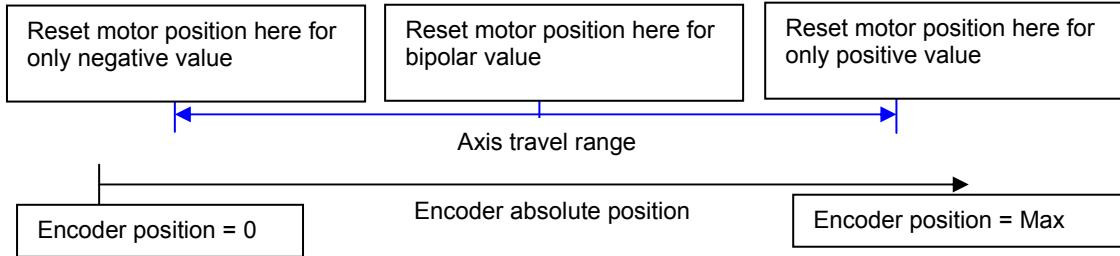

The displayed motor position range can be adjusted according to the application with:

- a positive value only
- or a negative value only
- or bipolar value.

When **Reverse motor position** is not selected:

When **Reverse motor position** is selected:

Object 0x312B,1 allows setting the Motor Zero at the current position:

- Place the motor at the desired Zero Position,
- drive must be disabled,
- write 0x312B,1=0x73626165
- save parameters into drive

The encoder offset is given in object 0x312D,5 (encoder unit) which must be stored in the parameter file.

The Motor Zero Position can be manually defined:

- drive is disabled,
- write offset value to 0x312D,5
- save parameters into drive
- restart 24 V to apply this offset.

#### Example 2:

Set 0x312D,5 = 0x400 0000, so Motor Zero Position is set in the middle of the encoder absolute position range, The absolute position value will be from -(Max\_value+1)/2 to (Max\_value+1)/2-1

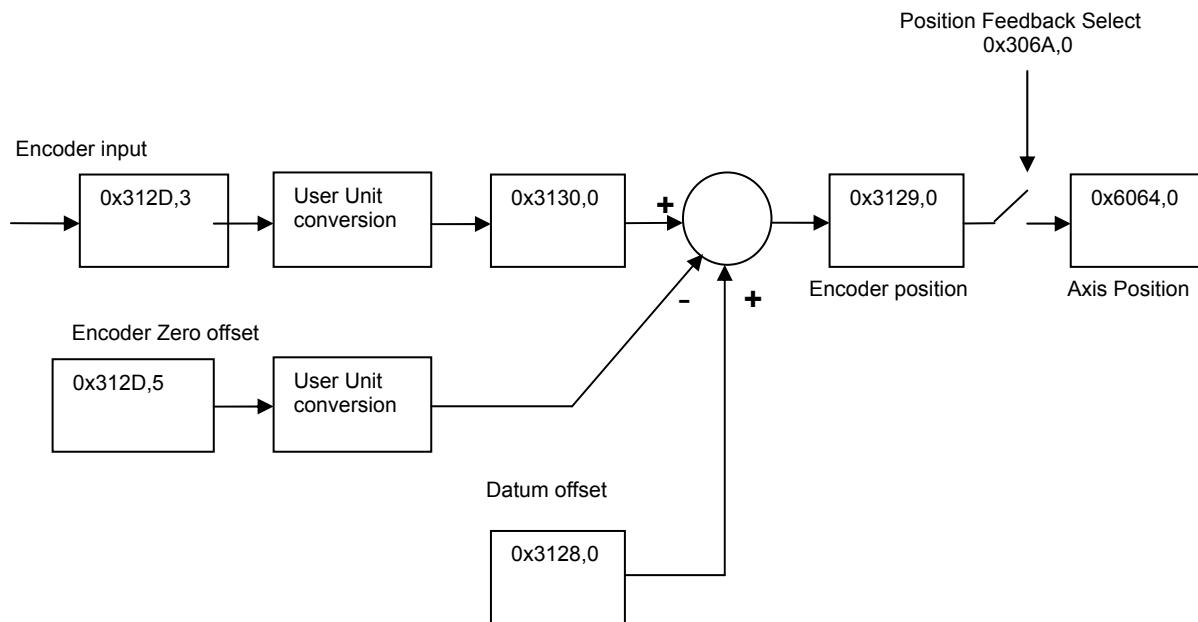

#### User Datum

The user position reference related to the mechanical machine can be defined with a homing operation, as usual. The encoder position offset from homing operation can be read with object 0x3128,0. After the homing operation, parameters need to be saved (object 0x3128,0 is saved in the parameter file). This operation needs to be carried out only once in the machine life-time.

The encoder position in user unit is defined by the relation below:  
 $[0x3129,0] = [0x3130,0] + [0x3128,0] - \text{user\_unit}([0x312D,5])$

0x3129,0 and 0x3130,0 and 0x3128,0 are in user unit, 0x312D,5 is in encoder unit.

If the position feedback is an encoder, then [0x6064,0] is the same as [0x3129,0].

### 3.2.2.8 - Factor and units

#### Factor and Units

The position unit is defined by object 0x6093

The velocity unit is defined by position unit per second.

The acceleration unit is defined by position unit per square second.

| Index  | Object | Name                        | Type       | Attr. |

| PDO Mapping   | No                        |
| Default Value | 4096                      |

|               |                             |
|---------------|-----------------------------|
| Sub Index     | 2                           |
| Description   | Position Factor Denominator |
| Data Type     | Unsigned32                  |
| Object Class  | all                         |
| Access        | rw                          |
| PDO Mapping   | No                          |
| Default Value | 4096                        |

The Denominator defines the increments in user unit for one motor revolution.

The Numerator defines the increments in motor unit for one motor revolution. This value must be set at 4096.

Motor\_position = Numerator / Denominator \* User\_position

#### Example:

1 motor revolution corresponds to a displacement of 5 mm on the load.

The desired user resolution is in  $\mu\text{m}$ .

Setting parameters:

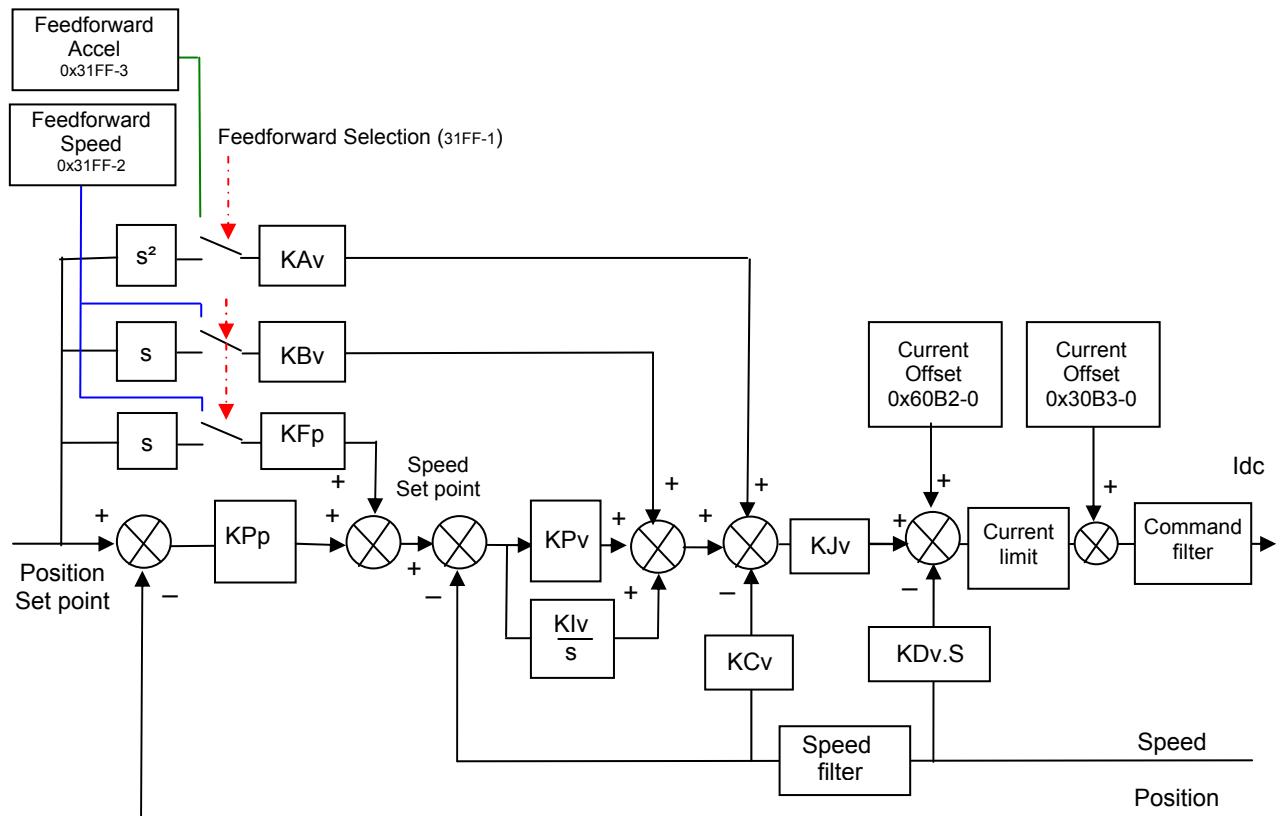

Numerator = 4096

Denominator = 5000

User unit =  $\mu\text{m}$

### 3.2.2.9 - Servo Loops

#### SERVO CONTROLLER STRUCTURE

**Speed loop** gains are the most critical to adjust because they greatly depend on the mechanical load characteristics (inertias, frictions, coupling stiffness, resonances,...).

- **Proportional speed gain (KPv)**: defines the proportional gain of the controller which acts on the speed error. The higher this parameter value, the faster the speed loop response.

- **Integral speed gain (KIv)**: defines the integral gain of the controller which acts on the speed error. The higher this parameter value, the better the axis stiffness.

- **Integrator low frequency limit (Klv in Hz)**: defines the low frequency value from where the controller integrator term is saturated. This parameter is used for reducing the motor heating in applications with large dry frictions due to the mechanical load.

- **Damping gain (KCv)**: defines the proportional gain of the controller which acts only on the speed feedback. This parameter allows reducing the speed loop overshoot in response to a step like set point change.

- **Derivative speed gain (KDv)**: defines the derivative gain of the controller which acts only on the speed feedback.

- **Derivator high frequency limit (KDvf in Hz)**: defines the high frequency value from which the controller derivative term is saturated.

- **Gain scaling factor (KJv)**: defines a multiplying factor for all speed regulator gains except the derivative gain KDv. This parameter is scaling the speed regulator gains in order to avoid any saturation when large values are required. This parameter also allows adjusting the servo loop stability in case of load inertia variations.

The **Current command filter** is a 3rd order, low-pass type filter, with 3 adjustable cut-off frequencies. Each cut-off frequency value can be freely adjusted according to the application, for the filtering of high frequency noise or of mechanical resonances.

The **Speed measurement filter** is a 1st order, low-pass type filter, with 3 selectable time constant values. The higher the time constant value, the lower the speed measurement noise, but also the lower the speed loop gains because of the increased speed measurement delay. The **Speed measurement filter** time constant is selected according to the motor position sensor resolution and the acceptable noise level in the speed measurement.

**Position loop** gains mainly influence the servo motor behaviour during the displacements (following error, position overshoot, audible noise, ...).

- **Proportional position gain (KP<sub>P</sub>)**: defines the proportional gain of the controller which acts on the position error. The higher this parameter value, the better the axis stiffness and the lower the following error.
- **Feedforward speed 1 gain (KF<sub>P</sub>)**: defines the feedforward speed amplitude corresponding to the speed input command. This term allows reducing the following error during the motor displacement. Its value is set at the maximum (65536) after the auto-tuning procedure, if a following error as small as possible is required.
- **Feedforward speed 2 gain (KB<sub>V</sub>)**: defines the feedforward speed amplitude corresponding to the viscous frictions. This term allows reducing the viscous friction effect during the motor displacement. The gain value is equal to the damping gain value + the viscous friction compensation term. After the auto-tuning procedure, the feedforward speed 2 gain is set equal to the damping gain value, if a following error as small as possible is required. The viscous friction compensation term can be calculated by measuring the current/speed ratio at various motor speed values.
- **Feedforward acceleration gain (KA<sub>V</sub>)**: defines the feedforward acceleration amplitude corresponding to the acceleration input command. This term allows reducing the following error during the motor acceleration and deceleration phases. Its value is calculated by the amplifier during the auto-tuning procedure, if a following error as small as possible is required.

When the **auto-tuning** procedure is executed, the motor + mechanical load specifications are identified and the appropriate gain values are calculated according to the user selected requirements (controller type, filter type, bandwidth value, ...). All gain values can then be manually modified by the user, if required.

The choice of the time interval for speed measurement (speed measurement filter) allows selecting the speed measurement resolution value according to the position sensor resolution value:

$$\text{speed resolution (rpm)} = 60000 / \text{position sensor resolution (ppr)} / \text{time interval (ms)}.$$

The higher the time interval value, the better the resolution, but also the lower the servo loop gains because of the increased speed measurement delay.

The choice of the anti-resonance filter is necessary in case of loud noise in the motor due to the motor/load coupling elasticity.

The choice of the maximum stiffness filter allows getting the maximum stiffness on the motor shaft with regard to the torque disturbances. However, this choice is only possible without any resonance due to the motor/load coupling elasticity.

The choice of the speed loop bandwidth defines the cut-off frequency value of the closed loop frequency response (Low = 50 Hz, Medium = 75 Hz, High = 100 Hz).

The choice “**minimum following error**” allows getting an accurate following of the position reference value during the whole motor displacement. In this case, all feedforward gain values are calculated.

The choice “**minimum position overshoot**” allows getting a motor positioning without any overshoot of the target position. In this case, all feedforward gain values are set at 0, and the motor position is lagging with regard to the position reference value during the whole motor displacement.

| Unit         | User Velocity Unit    |

The "Velocity Actual Value" gives the value of the actual motor velocity in user unit. This signal is filtered by a low-pass filter defined by 0x306C.

Object 0x3069 gives the same Actual Velocity but in rpm unit.

Object 0x30F8-2 gives the actual velocity without the low-pass filter.

| Description   | Feedforward Speed 2 Gain<br>This gain value is equal to the damping speed gain value + Feedforward friction gain value. The feedforward friction gain allows cancelling the load viscous friction effect (load viscous friction torque is proportional to axis speed). This feedforward term allows reducing the following error during the motor acceleration and deceleration phases. |
| Data Type     | Unsigned16                                                                                                                                                                                                                                                                                                                                                                              |

| Value Range   | 0..0xFFFFFFFF              |
| Default Value | -                          |

This object defines the tolerance for position value:

$$| \text{PosDemand} - \text{PosActual} | < \text{FollowingErrorWindow}$$

If the value of the following error window is FFFF FFFFh, the following control shall be switched off.

### 3.2.2.10 - Auto-tuning

#### Auto-tuning Parameters

|                    |                        |
|--------------------|------------------------|
| Index              | 0x3425                 |
| Name               | Auto-tuning parameters |
| Object Code        | ARRAY                  |
| Number of Elements | 4                      |

#### Value Description

All these parameters must be set before starting the auto-tuning by 0x3426.

|               |                       |
|---------------|-----------------------|
| Sub Index     | 1                     |
| Description   | Auto-tuning Bandwidth |
| Data Type     | Unsigned16            |
| Object Class  | -                     |
| Access        | rw                    |
| PDO Mapping   | No                    |
| Value Range   | 0..2                  |
| Default Value |                       |

This parameter defines the auto-tuning bandwidth:

| Value | Bandwidth        |
|-------|------------------|
| 0     | Low Bandwidth    |
| 1     | Medium Bandwidth |
| 2     | High Bandwidth   |

|               |             |
|---------------|-------------|
| Sub Index     | 2           |
| Description   | Filter type |
| Data Type     | Unsigned16  |
| Object Class  | -           |
| Access        | rw          |
| PDO Mapping   | No          |
| Value Range   | 0..2        |
| Default Value |             |

This parameter defines the auto-tuning filter:

| Value | Filter                |
|-------|-----------------------|
| 0     | Standard filter       |
| 1     | Anti-resonance filter |
| 2     | High stiffness filter |

|               |              |
|---------------|--------------|
| Sub Index     | 3            |
| Description   | Speed Filter |
| Data Type     | Unsigned16   |
| Object Class  | -            |
| Access        | rw           |
| PDO Mapping   | No           |
| Value Range   | 0..2         |
| Default Value |              |

This parameter defines the speed filter:

| Value | Filter                     |
|-------|----------------------------|
| 0     | auto-select by auto-tuning |
| 1     | 0.5 ms                     |
| 2     | 1 ms                       |
| 3     | 2 ms                       |

|               |                                      |
|---------------|--------------------------------------|
| Sub Index     | 4                                    |
| Description   | Auto-tuning Application Requirements |
| Data Type     | Unsigned16                           |
| Object Class  | -                                    |
| Access        | rw                                   |
| PDO Mapping   | No                                   |
| Value Range   | 0..1                                 |
| Default Value |                                      |

| Value | Application Requirements |
|-------|--------------------------|
| 0     | Minimum tracking error   |
| 1     | Minimum overshoot        |

### Auto-tuning Procedure

|              |                             |
|--------------|-----------------------------|
| Index        | 0x3426                      |
| Name         | Start Auto-tuning procedure |
| Object Code  |                             |
| Data Type    | Unsigned32                  |
| Object Class | all                         |
| Access       | rw                          |
| PDO Mapping  | No                          |

Parameters for Auto-tuning (0x3425) must be previously set.

In order to avoid running the auto-tuning procedure by mistake, the auto-tuning is only executed when a specific signature is written to this sub-index. The signature is 'atun'.

Signature = 0x6E757461

Writing 0 to this object when auto-tuning is running will abort the procedure.

When reading, this object returns the operation status:

| Read Value | Meaning                    |
|------------|----------------------------|
| 0          | Procedure never executed   |
| 1          | Cannot execute             |
| 2          | Procedure running          |
| 3          | Procedure aborted by user  |
| 4          | Procedure stopped on error |
| >= 5       | Procedure done             |

When running, the BUSY bit of status word (0x6041) is set.

Remark:

The parameters calculated by the auto-tuning depend on which mode it is executed (for example, if auto-tuning is executed in Profile Velocity Mode, the position loop gain will be equal to 0).

### 3.2.2.11 - Save / Load parameters

#### Internal Load/Save Command

The ServoPac TT drive can store parameters in its internal flash memory:

Writing to object 0x1010 initiates the saving procedure which stores the drive parameters in its internal flash memory (inside a file called DRIVEPAR.TXT).

Writing to object 0x1011 initiates the restoring procedure which re-loads the drive parameters from its internal flash memory (from the previously saved DRIVEPAR.TXT file).

#### Store parameters

|                    |                  |
|--------------------|------------------|
| Index              | <b>0x1010</b>    |

| Loading of the drive parameters (DRIVEPAR.TXT)                                                       | 0x64616F6C       | "load"       |
| Loading of the USER_PAR.TXT file<br>loads parameters from USER_PAR.TXT file into memory.             | 0x7273756C       | "lusr"       |
|                                                                                                      |                  |              |
| Loading of the SEQUENCE.TXT file<br>loads parameters from SEQUENCE.TXT file into sequence<br>memory  | 0x7165736C       | "lseq"       |
| Merging of the SEQUENCE.TXT file<br>merges parameters from SEQUENCE.TXT file into sequence<br>memory | 0x7165736D       | "mseq"       |

While operation is running, busy bit in status word (0x6041) is set.

If the Hiperface® encoder is selected when loading drive parameters, the encoder reference (0x312D,5 and 0x3125,6) and homing offset (0x3128,0) are also loaded from the Hiperface® Encoder non volatile memory. After a reset of the Hiperface® error, these objects are also reloaded.

### 3.2.3 - OPERATION MODES

#### 3.2.3.1 - Supported Drive Modes

##### Supported Drive Modes

A drive can support more than one and several distinct modes of operation. This object gives an overview of the implemented operating modes in the device. This object is read only.

| Access        | ro                        |
| PDO Mapping   | Yes                       |
| Default Value | -                         |

### 3.2.3.3 - Profile Position Mode

#### Profile Position Mode

In this mode, a trapezoidal trajectory generator gives the drive the possibility to execute a positioning with preset parameters as target position, profile speed and acceleration.

In profile position mode, these bits in the control word are relative to the control of the trajectory:

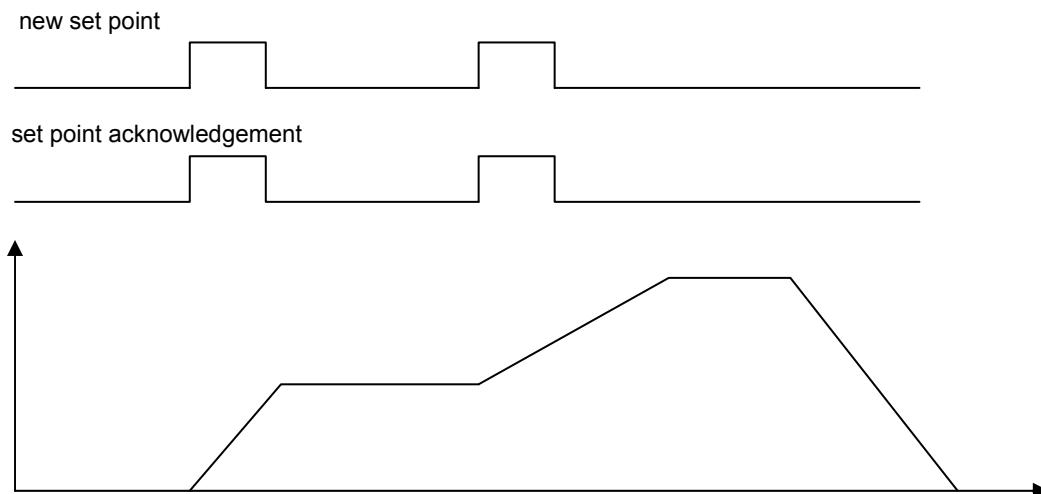

| Bit Number | Profile Position Mode      |
|------------|----------------------------|
| 4          | new set point              |
| 5          | change set immediately     |
| 6          | 0: absolute<br>1: relative |

The movement will be triggered by a rising edge of bit 4 (new\_set\_point) of the control word. The acknowledgement of the new set point is confirmed by bit 12 (setpoint acknowledgement) of the status word. The target position will be taken as relative to the current position if bit 6 of control word = 1.

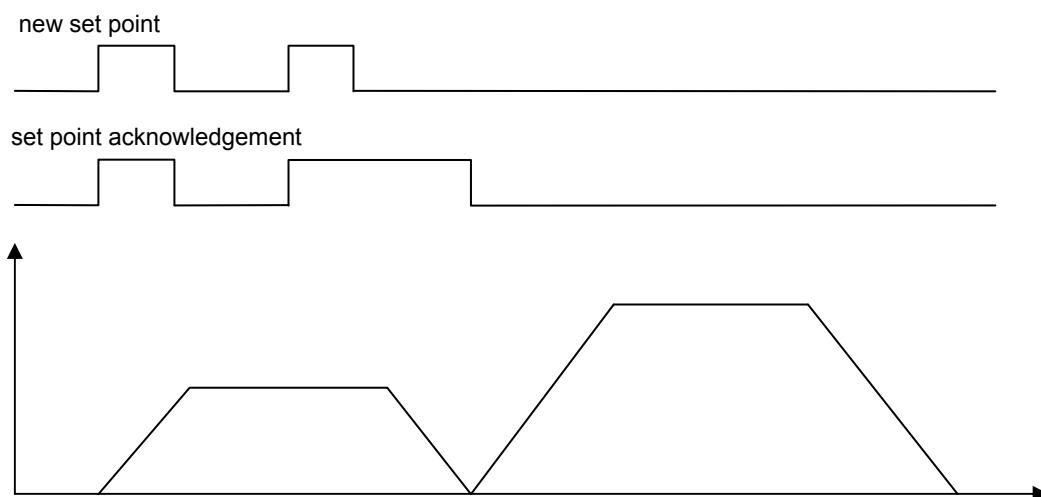

The speed profile is trapezoidal (motion profile type = 0) or S-curve (motion profile type = -1).

### Change setpoint immediately

Bit change\_set\_immediately = 1 :

Bit change\_set\_immediately = 0 :

| Name          | Target Position                           |
| Object Code   | VAR                                       |
| Data Type     | Integer32                                 |
| Object Class  | pp                                        |
| Access        | rw                                        |
| PDO Mapping   | Yes                                       |
| Unit          | User Position Unit                        |
| Value Range   | (-2 <sup>31</sup> )..(2 <sup>31</sup> -1) |
| Default Value | 0                                         |

**Target position** is the final position where the motor will move to in profile position mode. The start position is the current position. The positioning begins with rising edge of bit 4 of the control word (new set point). Bit 6 of control word indicates if the target position is absolute (=0) or relative (=1) movement.

| Index         | 0x6080          |
|---------------|-----------------|
| Name          | Max Motor Speed |
| Object Code   | VAR             |
| Data Type     | Integer32       |
| Object Class  | all             |
| Access        | rw              |
| PDO Mapping   | No              |
| Unit          | rpm             |
| Value Range   | 100...60000     |
| Default Value | 3000            |

The *Max. motor speed* defines the maximum speed the drive can reach. To avoid a saturation of the servo loop, the running speed must be less than *Max. motor speed* (depends on the overshoot accepted for the servo loop response).

This parameter modifies the value of the Max Profile Velocity 0x607F.

| Index         | 0x6081             |
|---------------|--------------------|
| Name          | Profile Velocity   |
| Object Code   | VAR                |
| Data Type     | Unsigned32         |
| Object Class  | pp                 |
| Access        | rw                 |
| PDO Mapping   | Possible           |
| Unit          | User Velocity Unit |
| Value Range   | -                  |
| Default Value | 0x1000             |

The *Profile Velocity* is the running velocity for a positioning. If the positioning is too short, the profile velocity may not be reached.

| Index         | 0x6082             |
|---------------|--------------------|
| Name          | End Velocity       |

| PDO Mapping   | No                                        |
| Value Range   | 0 -> Trapezoidal profile<br>-1 -> S-Curve |
| Default Value | 0                                         |

The S-curve is defined by a polynomial. The acceleration profile is therefore parabolic.

| Unit          | User Position Unit |
| Default Value | 0                  |

The *Position Window* defines a symmetrical range of accepted positions relatively to the target position. If the motor current position is within the position window, this target position is considered as reached (bit 10 or status word - Target Reached – is set). If the position window value is 0, the position window control is not active.

When the actual position is within the *Position Window* during the defined *Position Window Time*, the corresponding bit 10 *Target reached* in the *StatusWord* will be set at 1.

| Value Range   | 0...(2 <sup>32</sup> –1) |
| Default Value | 0                        |

The **Max. Profile Velocity** is the maximum speed allowed in any direction during a profiled move.  
This parameter limits the input velocity reference in:

- profile position mode (0x6081),
- profile velocity mode (0x60FF),
- profile position function block and profile velocity function block in servo mode.

## Position Profile Speed Modulation Input Source

|               |                                                |
|---------------|------------------------------------------------|
| <b>Index</b>  | <b>0x3081</b>                                  |
| Name          | Position Profile Speed Modulation Input Source |
| Description   | Index/sub-index of input data                  |
| Data Type     | Unsigned32                                     |
| Object Class  | sm, pp, sq                                     |
| Access        | rw                                             |
| PDO Mapping   | No                                             |
| Default Value | 0                                              |
| Value         | See below                                      |

This object allows connecting any dataflow as a speed modulation of the Profile generator in Profile Position Mode or Profile Generator Function Block in Servo Mode or Sequence Mode.

The structure of the entries is the following:

|                |                     |
|----------------|---------------------|
| MSB            | LSB                 |
| Index (16-bit) | Sub-index (8-bit) 0 |

The modulation value is between 0 and 0x7FFF. A modulation value of 0x7FFF means 100 % of the programmed velocity.

If the input source value is negative, then the modulation value is the absolute value.

### Example:

0x3081,0 = 0x30830000

connects 0x3083 as the modulation speed for Profiles Position.

## Position Profile Speed Modulation Configuration

| Description   | This object can be connected as the dataflow of the Position Profile Speed Modulation Input Source (0x3081) |
| Data Type     | Integer16                                                                                                   |
| Object Class  | all                                                                                                         |
| Access        | rw                                                                                                          |
| PDO Mapping   | Yes                                                                                                         |
| Default Value | 0                                                                                                           |

## Axis Type

|               |               |
|---------------|---------------|
| <b>Index</b>  | <b>0x3360</b> |
| Name          | Axis Type     |
| Object Code   | VAR           |
| Data Type     | Unsigned8     |
| Object Class  | all           |
| Access        | rw            |
| PDO Mapping   | No            |
| Default Value | 0             |

This parameter defines the axis type: linear or rotating.

A linear axis has its software position limit active.

| <b>Value</b> | <b>Function</b> |
|--------------|-----------------|
| 0            | rotating        |
| 1            | linear          |

## Software Position Range Limit

The Software Position Range Limit defines a Positive Position Limit and a Negative Position Limit, which act as hardware limit switches.

The Software Position Range Limit is activated when Axis Type (0x3360) is linear.

| Value       |                         |

### 3.2.3.4 - Homing Mode

When the feedback sensor does not give the absolute position, the homing mode is the right way to set up the motor to a known position. This position can be detected by using several signals such as positive or negative limit switch, home switch, index pulse or mechanical limit. The choice of the homing method depends on those signals and on the direction of the starting movement.

The drive generates the trajectory according to the homing method. This is the reason why the position loop of the drive is used.

Graphical representation of the trajectories as a function of the input signals:

| Index  | Object | Name                | Type       | Attr. |
|--------|--------|---------------------|------------|-------|
| 0x607C | VAR    | Home Offset         | Integer32  | rw    |
| 0x6098 | VAR    | Homing Method       | Integer8   | rw    |
| 0x6099 | ARRAY  | Homing Speeds       | Unsigned32 | rw    |
| 0x609A | VAR    | Homing Acceleration | Unsigned32 | rw    |

Manufacturer Specific Objects:

| Index  | Object | Name                       | Type       | Attr. |
|--------|--------|----------------------------|------------|-------|
| 0x309C | VAR    | Homing Current Limit       | Unsigned16 | rw    |
| 0x309D | VAR    | End On Home Position       | Unsigned16 | rw    |
| 0x3218 | VAR    | Homing Operation Indicator | Unsigned16 | rw    |

The homing procedure is launched on rising edge of bit 4 of the Control Word and can be interrupted when clear.

Meanings of operation mode specific bits of the Status Word:

| Bit 13 | Bit 12 | Bit 10 | Definition                                  |
|--------|--------|--------|---------------------------------------------|
| 0      | 0      | 0      | Homing procedure in progress                |
| 0      | 0      | 1      | Homing procedure interrupted or not started |
| 0      | 1      | 0      | Homing reached, but target is not reached   |
| 0      | 1      | 1      | Homing procedure successfully completed     |
| 1      | 0      | 0      | Homing error occurred, velocity is not 0    |
| 1      | 0      | 1      | Homing error occurred, velocity is 0        |
| 1      | 1      | X      | reserved                                    |

If Bit 10 is set, this indicates that the velocity is 0.

If bit 12 is set, this indicates that the home position is known but not available.

Bit 12 is reset at 0:

- at power-up,
- if a sensor fault occurs,
- on homing error,
- when homing is starting,
- when bit 4 of the Control Word is at 0.

Bit 13 indicates a homing error:

- homing launched whereas the drive is not in "operation enabled" (except for homing method 35);
- homing launched with an unimplemented selected method.

Bit 13 is reset at 0:

- at drive power-up,
- on rising edge of bit 7 of the Control Word.

### **Homing Offset**

The Home Offset defines the position feedback value when the motor reaches the homing position.

| Index         | 0x607C                                     |
|---------------|--------------------------------------------|
| Name          | Home Offset                                |
| Object Code   | VAR                                        |
| Data Type     | Integer32                                  |
| Object Class  | hm                                         |
| Access        | rw                                         |
| PDO Mapping   | No                                         |
| Unit          | User position unit                         |
| Value Range   | (-2 <sup>31</sup> ). .(2 <sup>31</sup> -1) |
| Default Value | 0                                          |

### **Homing Method**

The *Homing Method* defines various ways of the drive to search the homing position.

| Index         | 0x6098        |
|---------------|---------------|
| Name          | Homing Method |
| Object Code   | VAR           |
| Data Type     | Integer8      |
| Object Class  | hm            |
| Access        | rw            |
| PDO Mapping   | No            |
| Default Value | 23h           |

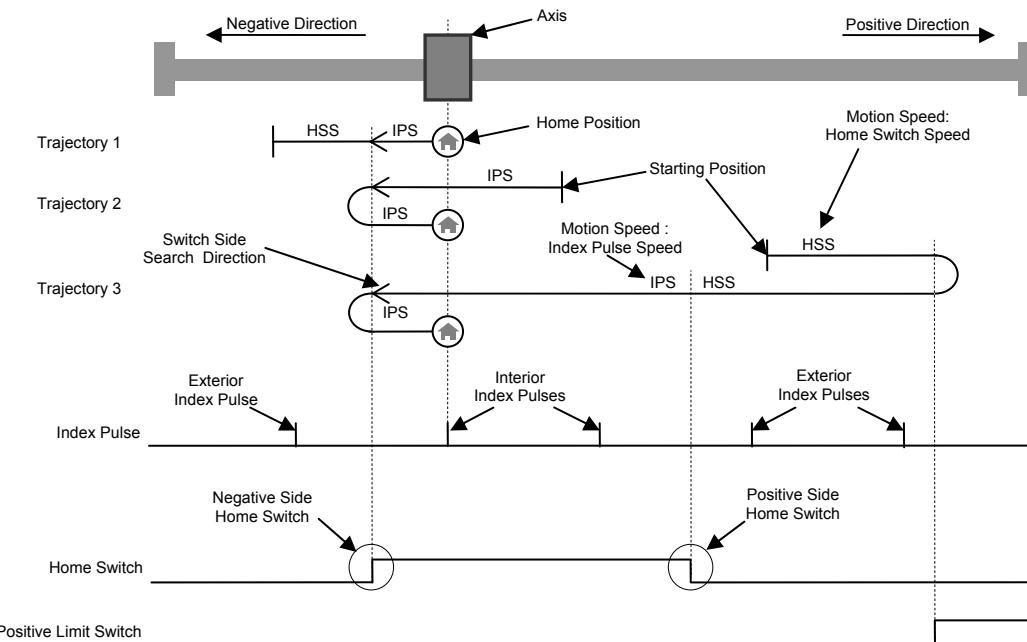

**Value Description**

Method supported: 1..14, 17..30, 33..35.  
 Methods specific: -1, -2, -3, -4.

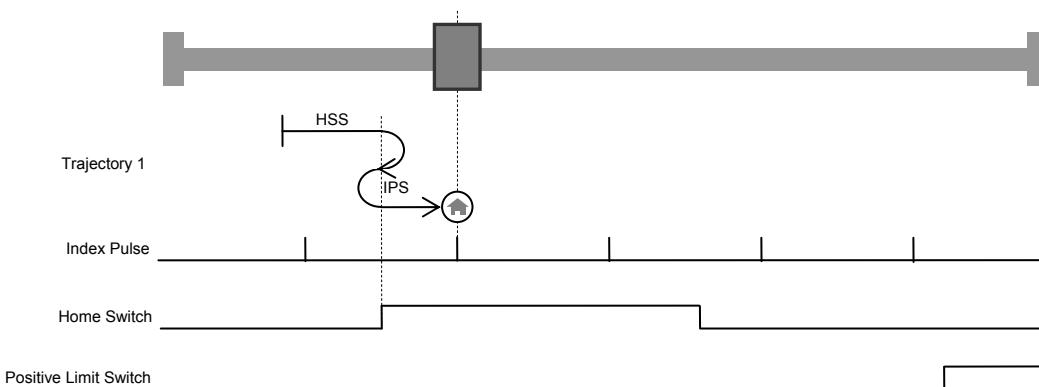

| Method | Search for Switch               | Search for Index Pulse | Remarks                                                            |
|--------|---------------------------------|------------------------|--------------------------------------------------------------------|
| 1      | Negative Limit Switch           | Exterior               |                                                                    |
| 2      | Positive Limit Switch           | Exterior               |                                                                    |
| 3      | Positive Home Switch            | Exterior               |                                                                    |

| 34     |                                 | First Index Pulse      | Positive Initial Move.                                             |
| 35     |                                 | -                      | Homing On Current Position                                         |
| -1     | Mechanical Limit, Negative Move | First Index Pulse      |                                                                    |
| -2     | Mechanical Limit, Positive Move | First Index Pulse      |                                                                    |
| -3     | Mechanical Limit, Negative Move | -                      |                                                                    |
| -4     | Mechanical Limit, Positive Move | -                      |                                                                    |

According to the table above, each homing method can be detailed using a diagram representing all of the possible trajectories.

Homing Method 8 is taken as an example:

For simplifying diagrams, the trajectory of the switch side search is not explicitly drawn. However, an arrow indicates the direction used to search a switch side. Hence, trajectory 1 of homing method 8 is explained in the following diagram:

The following explanation describes only trajectory 1 of homing method 8 taken above as an example. Using homing method 8, the initial direction of the movement is positive, except if the home switch is active at the motion start. So, the negative side of the home switch is first searched in the positive direction with the Home Switch Speed. When the activation of the home switch is detected, the drive reverses to look for the home switch deactivation. As the home switch has been found, the speed is the slowest home speed, namely the Index Pulse Speed. Once the deactivation of the home switch has been found, the drive reverses to position to look for the Index Pulse. At this stage, depending on the position sensor, the home position will directly be reached, for example a resolver. For sensors like incremental encoders, a search of Index Pulse is achieved in the positive direction and then the drive reverses to position on the captured Index Pulse position.

## Homing Speeds

*Homing Speeds* defines the motor speed when searching the homing position.

| Index              | 0x6099        |

| PDO Mapping   | No                     |
| Unit          | User acceleration unit |
| Default Value | 00010000h              |

## Homing Current Limit

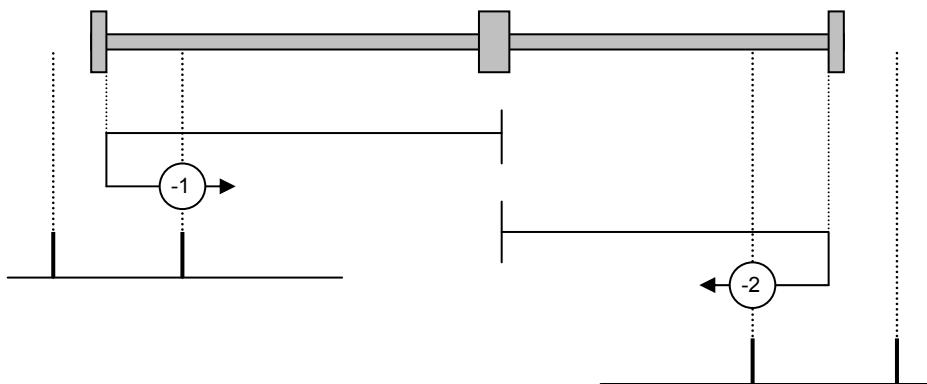

The "Homing current limit" defines the limit of current during the homing on the mechanical limit. The value is defined as a percent of the drive maximum current (defined by object 6510h sub-index 1).

| Index         | 0x309C                     |
|---------------|----------------------------|
| Name          | Homing Current Limit       |
| Object Code   | VAR                        |
| Data Type     | Unsigned16                 |
| Object Class  | hm                         |
| Access        | rw                         |
| PDO Mapping   | No                         |
| Unit          | %                          |
| Conversion    | 0 to 0x3FFF -> 0% to 100 % |
| Default Value | 0x0400                     |

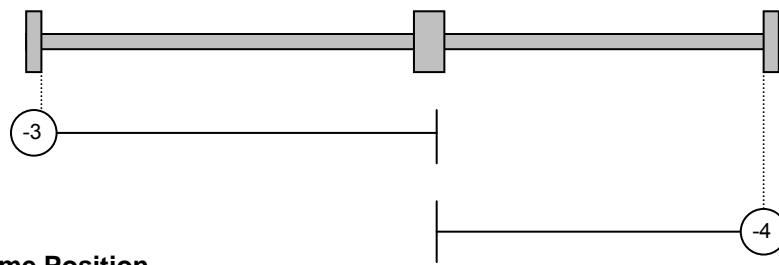

## Functional Description

The "Homing Current Limit" parameter defines the limit of current in the motor during the homing procedure. When the mechanical limit is reached, the current in the motor increases up to this limit and the motor speed is 0. This position will be taken as the homing position. An offset value (object 607Ch) can be used to preset the homing position value.

Methods -1 and -2 define the homing on the mechanical limit with index pulse.

Methods -3 and -4 define the homing on the mechanical limit.

## End on Home Position

This parameter allows the drive not reversing at the end of the homing.

If set at 1, it makes a move towards the home position when the homing is over. If cleared, the home position is found but not moved to.

| Index         | 0x309D               |
|---------------|----------------------|
| Name          | End on Home Position |
| Object Code   | VAR                  |
| Data Type     | Unsigned16           |
| Object Class  | hm                   |
| Access        | rw                   |
| PDO Mapping   | No                   |
| Default Value | 1                    |

## Homing Operation Indicator

|               |                            |
|---------------|----------------------------|
| <b>Index</b>  | <b>0x3218</b>              |
| Name          | Homing Operation Indicator |
| Object Code   | VAR                        |
| Data Type     | Unsigned16                 |
| Object Class  | all                        |
| Access        | rw                         |
| PDO Mapping   | No                         |
| Default Value | 0                          |

This object allows keeping the result of a homing operation:

- it is cleared when drive is switched on
- it is set if the position sensor is absolute multi-turn.
- it is set after a successful homing.
- it is cleared if the position sensor is lost (by any fault related to this sensor).
- if a special homing function is implemented in the master, the master needs to set this object after that special homing is complete.

### 3.2.3.5 - Interpolated Position Mode

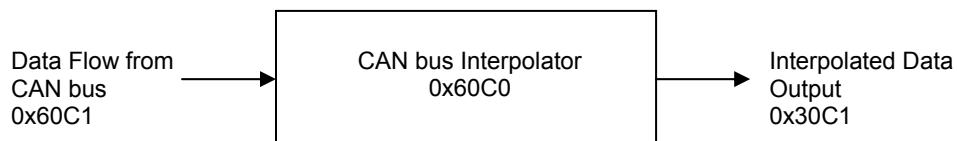

#### Interpolated Position Mode

The interpolated position mode is used to control several axes in coordination. The trajectory must be generated by the host controller and the elementary set point is sent at a fixed cycle time (same as communication cycle time) to all axes.

The cycle time synchronization of all axes is ensured by the SYNC message. The setpoint data flow must be sent in real-time.

The elementary set point could be only position if linear interpolation is chosen. The PV interpolation mode requires position and velocity for each set point. The P3 cubic interpolation mode requires only position set point because the interpolator is using the three last position set points. However, the interpolation error is inherent when the acceleration is changing with the P3 cubic interpolation mode.

Both cubic interpolation modes require high position resolution when operating at low speed values. At very low speed, the linear interpolation mode is giving best results.

The CAN bus Interpolator is running in any mode but the result of the interpolator (0x30C1) is applied to the position loop only in Interpolated Position Mode.

When using the linear interpolation, the feedforward acceleration term (KAv) must be cleared (see interpolation and servo loop). Only a PV or P3 interpolation can fully support a feedforward acceleration term.

| Index  | Object | Name                             | Type      | Attr. |
|--------|--------|----------------------------------|-----------|-------|
| 0x60C0 | VAR    | Interpolation Submode Select     | Integer16 | rw    |
| 0x60C1 | RECORD | Interpolation Data Record        |           | rw    |
| 0x60C4 | RECORD | Interpolation Data Configuration |           | rw    |
| 0x30C1 | VAR    | Interpolated Data Output         | Integer32 | rw    |

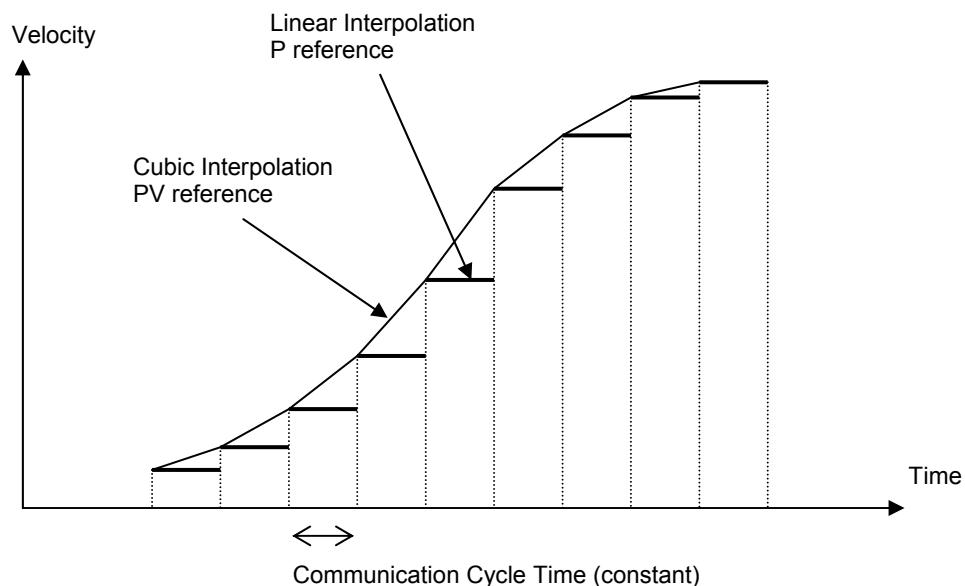

### Interpolation Submode Select

|               |                              |
|---------------|------------------------------|
| <b>Index</b>  | <b>0x60C0</b>                |
| Name          | Interpolation Submode Select |
| Object Code   | VAR                          |
| Data Type     | Integer16                    |
| Object Class  | ip                           |
| Access        | rw                           |
| PDO Mapping   | No                           |
| Value Range   | see below                    |
| Default Value | 0                            |

| Interpolation Submode Select | Description          |
|------------------------------|----------------------|
| 0                            | Linear interpolation |
| -1                           | PV interpolation     |
| -2                           | P3 interpolation     |

When in linear interpolation mode, only the first parameter of the interpolation data record is used. The data must be the position reference.

When in PV interpolation mode, the first parameter of the interpolation data record must contain the position reference and the second parameter of the interpolation data record contains the velocity reference.

Note: The velocity reference for each set-point must be the instantaneous velocity at this point (not the average velocity).

### Interpolation data record

|                    |                           |
|--------------------|---------------------------|
| <b>Index</b>       | <b>0x60C1</b>             |
| Name               | Interpolation data record |
| Object Code        | RECORD                    |
| Number of Elements | 2                         |

#### Value Description

|              |                                |
|--------------|--------------------------------|
| Sub Index    | 1                              |
| Description  | First parameter of ip function |
| Data Type    | Integer32                      |
| Object Class | ip                             |
| Access       | rw                             |
| PDO Mapping  | Possible                       |

This sub-index contains the position reference in IP mode.

|              |                                 |
|--------------|---------------------------------|
| Sub Index    | 2                               |
| Description  | Second parameter of ip function |
| Data Type    | Integer32                       |
| Object Class | ip                              |
| Access       | rw                              |
| PDO Mapping  | Possible                        |

This sub-index contains the speed reference in IP mode if the interpolation submode select (0x60C0) is -1 (interpolation PV). Otherwise it is not used.

#### Absolute 16-bit Position Reference for IP mode

|               |                                    |
|---------------|------------------------------------|
| <b>Index</b>  | <b>0x3350</b>                      |
| Name          | Absolute 16-bit Position Reference |
| Object Code   | VAR                                |
| Data Type     | Unsigned8                          |
| Object Class  | ip                                 |
| Access        | rw                                 |
| PDO Mapping   | No                                 |
| Value Range   | 0..1                               |
| Default Value | 0                                  |

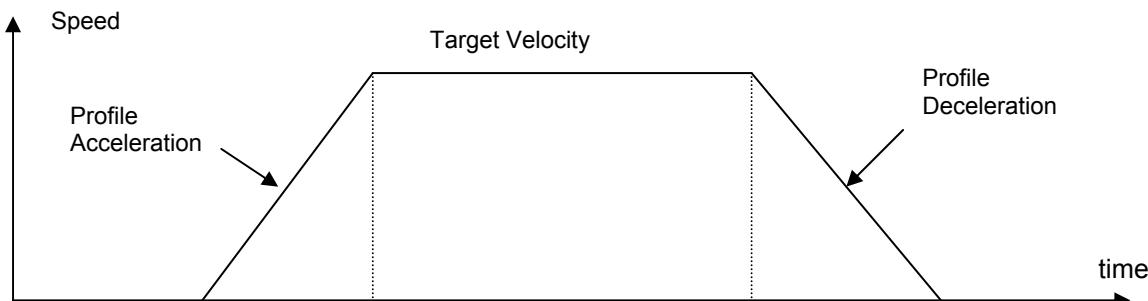

The position reference in interpolated position mode can be defined as 16-bits only. This is to reduce the bus traffic.

When in 16-bit mode (object 3350h = 1), the position reference in object 60C1-1 via PDO is set at 16 bits and the drive calculates the upper word. At the beginning, it is necessary to set the upper word with object 60C1-1 via SDO (Integer32). The mapping of RPDO must be changed to object 60C1 sub-index 1 with 16-bit length.

### 3.2.3.6 - Profile Velocity Mode

#### Profile Velocity Mode

The profile velocity mode authorizes the drive to operate with a velocity reference. Only speed loop and current loop are closed in this mode.

| Index  | Object | Name                        | Type       | Attr. |

| Access        | rw                     |
| PDO Mapping   | No                     |
| Unit          | User acceleration unit |
| Value Range   | -                      |
| Default Value | 0x10000                |

The **Velocity Window** defines a symmetrical range of accepted velocity relatively to the target velocity. If the motor current velocity is within the velocity window, this target velocity is considered as reached (bit 10 of status word - Target Reached – is set). If the velocity window value is 0, the velocity window control is not active.

| Index         | 0x606D          |
|---------------|-----------------|
| Name          | Velocity Window |
| Object Code   | VAR             |
| Data Type     | Unsigned32      |
| Object Class  | pv              |
| Access        | rw              |
| PDO Mapping   | No              |
| Unit          | Velocity Unit   |
| Default Value | 0               |

When the actual velocity is within the **Velocity Window** during the defined **Velocity Window Time**, the corresponding bit 10 Target reached in the StatusWord will be set at 1.

| Index         | 0x606E               |
|---------------|----------------------|
| Name          | Velocity Window Time |

## Profile Velocity Mode Input Source

| Index         | 0x30FF                                                 |
|---------------|--------------------------------------------------------|
| Name          | Profile Velocity Mode Input Source for Target Velocity |
| Description   | Index/sub-index of input data                          |
| Data Type     | Unsigned32                                             |
| Class         | pv                                                     |
| Access        | rw                                                     |
| PDO Mapping   | No                                                     |
| Value         | See below                                              |
| Default Value | 0x60FF0000                                             |

This object allows connecting any 32-bit dataflow as target velocity for the Profile Velocity Mode.

The structure of the entries is the following:

| MSB            | LSB                 |
|----------------|---------------------|
| Index (16-bit) | Sub-index (8-bit) 0 |

Example:

0x30FF,0 = 0x30F10200

connects the analog input as the target velocity for Profile Velocity Mode.

### 3.2.3.7 - Profile Torque Mode

#### Profile Torque Mode

In this mode, the drive operates only with current loops and there is no speed or position control.

#### Object Dictionary Entries

| Index  | Object | Name                       | Type       | Attr. |
|--------|--------|----------------------------|------------|-------|
| 0x6071 | VAR    | Target Torque              | Integer16  | rw    |
| 0x3071 | VAR    | Target Torque Input Source | Unsigned32 | rw    |
| 0x6087 | VAR    | Torque Slope               | Unsigned32 | rw    |
| 0x6088 | VAR    | Torque Profile Type        | Integer16  | rw    |
| 0x60B2 | VAR    | Offset Torque              | Integer16  | rw    |
| 0x6074 | VAR    | Torque Demand Value        | Integer16  | ro    |
| 0x6077 | VAR    | Torque Actual Value        | Integer16  | ro    |

| PDO Mapping   | Possible                               |
| Unit          | per thousand of rated current (0x6075) |
| Value Range   | -                                      |
| Default Value | 0                                      |

## Profile Torque Mode Input Source

|               |                                                    |
|---------------|----------------------------------------------------|
| <b>Index</b>  | <b>0x3071</b>                                      |
| Name          | Profile Torque Mode Input Source for Target Torque |
| Description   | Index/sub-index of input data                      |
| Data Type     | Unsigned32                                         |
| Class         | pt                                                 |
| Access        | rw                                                 |
| PDO Mapping   | No                                                 |
| Value         | See below                                          |
| Default Value | 0x60710000                                         |

This object allows connecting any 16-bit dataflow as a target torque for the Profile Torque Mode.

The structure of the entries is the following:

|                |                          |
|----------------|--------------------------|
| MSB            | LSB                      |
| Index (16-bit) | Sub-index (8-bit)      0 |

Example:

0x3071,0 = 0x30F10100

connects analog input 1 as the target torque for Profile Torque Mode.

This parameter defines the torque slope when the target torque is changed.

|               |                                          |
|---------------|------------------------------------------|
| <b>Index</b>  | <b>0x6087</b>                            |
| Name          | Torque Slope                             |
| Object Code   | VAR                                      |
| Data Type     | Unsigned32                               |
| Object Class  | pt                                       |
| Access        | rw                                       |
| PDO Mapping   | No                                       |
| Unit          | per thousand of rated current per second |
| Value Range   | -                                        |
| Default Value | 0x10000                                  |

"DC Voltage" gives the value of the DC voltage in the drive. This signal is filtered by a low-pass filter (0x3408-2)

|               |               |
|---------------|---------------|
| <b>Index</b>  | <b>0x6079</b> |
| Name          | DC Voltage    |

| Access        | ro            |
| PDO Mapping   | Yes           |
| Unit          | mV            |
| Value Range   | -             |
| Default Value | -             |

### 3.2.3.8 - Sequence Mode

The purpose of the sequencer mode is to allow basic moves.

A basic move is called "sequence" and a list of sequences can be pre-programmed and stored in the drive.

Each sequence is identified with a number (sequence number).

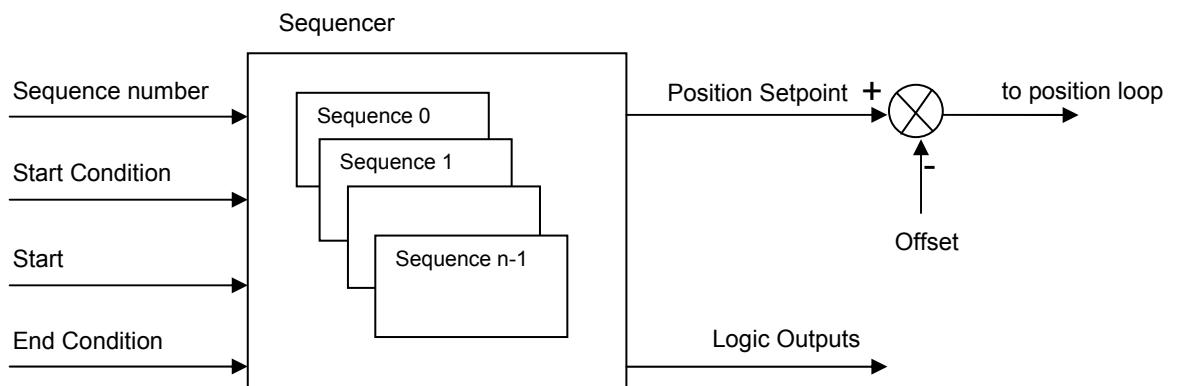

The maximum number of sequences for a given drive is shown in object 0x3612

The different sequence types are the following:

- Positioning sequence
- Homing sequence
- Speed sequence
- Torque sequence
- Gearing sequence

**NOTE:** depending on model and/or firmware version, not all sequence types above are supported. The sequence types supported are shown in object 0x360F

Various sequences can be sequentially linked together to build a complex move.

**Sequence Number:** allows the selection of the sequence to be executed. The "Sequence Number" can be connected to physical logic inputs or set via the fieldbus to select the sequence.

**Start Condition:** A Logic bit pattern can be defined as a condition for a sequence to be started. The "Start Condition" can be connected to physical logic inputs or to a variable via the fieldbus.

**Start:** A trigger signal (rising edge of start bit) allows starting the sequence which number is set by a sequence number and if the start condition is fulfilled.

If the start condition is not ok, the movement will not be executed until the start condition is valid.  
A sequence is started with bit 4 of control word (0x6040) and stopped with bit 5 of control word.

**End Condition:** In some sequences, if an "End Condition" is defined, the sequence will be over when the "End Condition" is valid. The "End Condition" is defined by bit patterns (bits equal to 0, bits equal to 1...), and can be connected to physical logic inputs or to a variable via the fieldbus.

Control Word (0x6040):

| Bit | Action           |
|-----|------------------|
| 4   | ↑ start sequence |
| 5   | 1 stop sequence  |
| 6   | reserved         |

Status Word (0x6041):

| Bit | Action         |
|-----|----------------|
| 10  | Target Reached |
| 12  | POS            |
| 13  | SEQ            |

## Sequence Chaining

The sequence chaining is controlled by the "SeqNext", "SeqCount", "SeqLink" and "StartCond" parameters.

## Sequence Parameters

The parameters of all sequences are stored in a RAM memory (sequence memory).

These sequence parameters can be set:

- by parameter values defined in a sequence file named SEQUENCE.TXT (see Sequence File format).
- by direct access to the sequence parameters via appropriate objects.

## Sequence Files

Loading a sequence file:

- all sequence parameters in the sequence memory will be erased by sequences defined in SEQUENCE.TXT
- if a sequence is not defined in SEQUENCE.TXT, then the sequence will be cleared.
- the SEQUENCE.TXT file will be loaded into the sequence memory when the 24 V supply is applied
- the SEQUENCE.TXT file will be loaded into the sequence memory when writing into object 0x1011 with signature = 0x7165736C (lseq)

Merging a sequence file:

- only sequences defined in SEQUENCE.TXT will be loaded into the sequence memory; other sequences in the memory are not modified.
- the SEQUENCE.TXT file can be merged in sequence memory when writing into object 0x1011 with signature = 0x7165736D (mseq).

## Object Definition

### Sequence Control

These objects allow controlling the execution of a sequence.

| Index  | Object | Name                        | Type       | Attr. |
|--------|--------|-----------------------------|------------|-------|
| 0x3601 | ARRAY  | Sequence Inputs             |            | rw    |
| 0x3602 | ARRAY  | Sequence Outputs            |            | rw    |
| 0x3603 | VAR    | Minimum Sequence Pulse      | Unsigned16 | rw    |
| 0x3604 | RECORD | Output Pulse Configuration  |            | rw    |
| 0x3605 | VAR    | Sequence phase              | Unsigned16 | rw    |
| 0x360B | VAR    | Sequence Capture Position   | integer32  | rw    |
| 0x360F | VAR    | Supported Sequence Type     | Unsigned16 | ro    |
| 0x3612 | VAR    | Maximum Sequences Supported | Unsigned16 | ro    |

### Sequence Parameters

These objects allow the direct access to any parameter of any sequence.

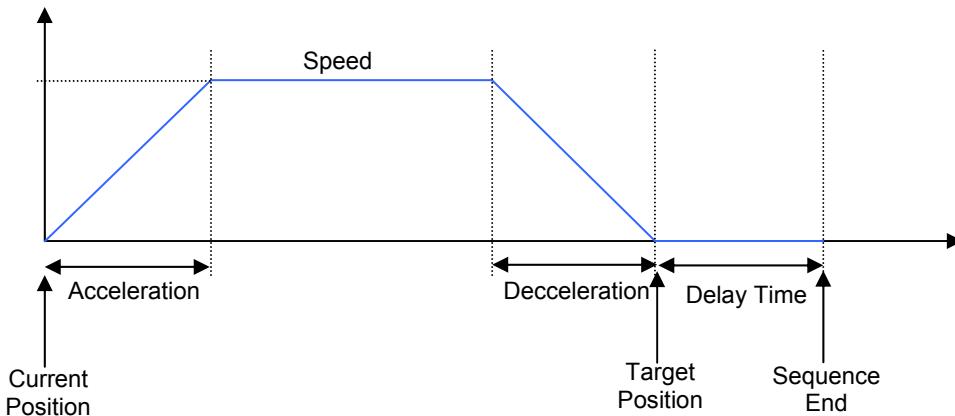

The selected sequence number is defined by object 0x3610, and all sequence parameters are accessed by object 0x3611.

| Index  | Object | Name                       | Type      | Attr. |
|--------|--------|----------------------------|-----------|-------|
| 0x3610 | VAR    | Sequence Parameters Number | integer16 | rw    |
| 0x3611 | RECORD | Sequence Parameters        |           | rw    |

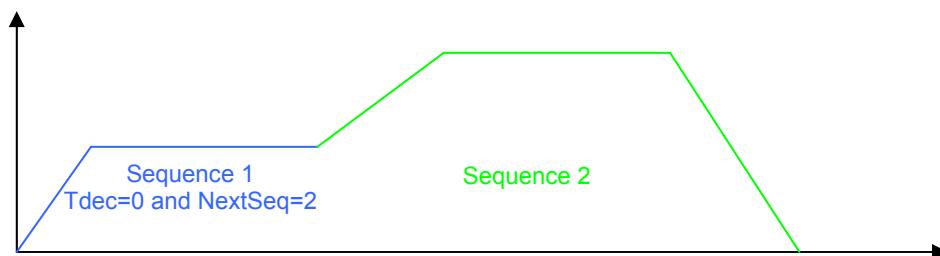

### 3.2.3.8.1 - Positioning Sequence

The main parameters of a positioning sequence are:

- The position to be reached (absolute or relative)
- The motion speed
- The acceleration time
- The deceleration Time
- The delay time at the end of the motion

Example of 2 positioning sequences without stopping (the deceleration ramp of the first sequence is 0).

Sequence 1:

```
SeqType = POS
Speed = 150000
AccelTime = 400
DecelTime = 0
NextSeq = 2
```

Sequence 2:

```
SeqType = POS
Speed = 250000
AccelTime = 300
DecelTime = 400
```

### Supported keywords and parameters for a positioning sequence

| Keyword   | Direct parameter entry | Description                                                                |
|-----------|------------------------|----------------------------------------------------------------------------|
| SeqType   | 0x3611-1               | value = POS for SEQUENCE.TXT file or value = 1 for direct parameter object |
| NextSeq   | 0x3611-2               | see sequence parameters                                                    |
| SeqCount  | 0x3611-3               | see sequence parameters                                                    |
| SeqLink   | 0x3611-4               | see sequence parameters                                                    |
| Trigger   | 0x3611-5               | see sequence parameters                                                    |
| Output    | 0x3611-6               | see sequence parameters                                                    |
|           | 0x3611-7               |                                                                            |
|           | 0x3611-8               |                                                                            |
| StartCond | 0x3611-9               | see sequence parameters                                                    |
|           | 0x3611-10              |                                                                            |
| Tempo     | 0x3611-23              | see sequence parameters                                                    |
| Speed     | 0x3611-15              | defines the speed setpoint of the sequence in velocity unit                |
| Speed2    | 0x3611-16              | defines the speed setpoint at the end of the sequence in velocity unit     |
| Accel     | 0x3611-17              | defines the acceleration time in user unit per square second               |
| Decel     | 0x3611-18              | defines the deceleration time in user unit per square second               |
| Position  | 0x3611-13              | defines the position setpoint in user unit                                 |
| EndCond   | 0x3611-11              | see sequence parameters                                                    |
|           | 0x3611-12              |                                                                            |

#### 3.2.3.8.2 - Homing Sequence

The Home sequence allows performing a homing procedure.

The main parameters of a home sequence are:

- Home Offset
- Home method
- Speeds
- Acceleration
- Current limit (Torque Limit) for method -1, -2, -3 and -4.

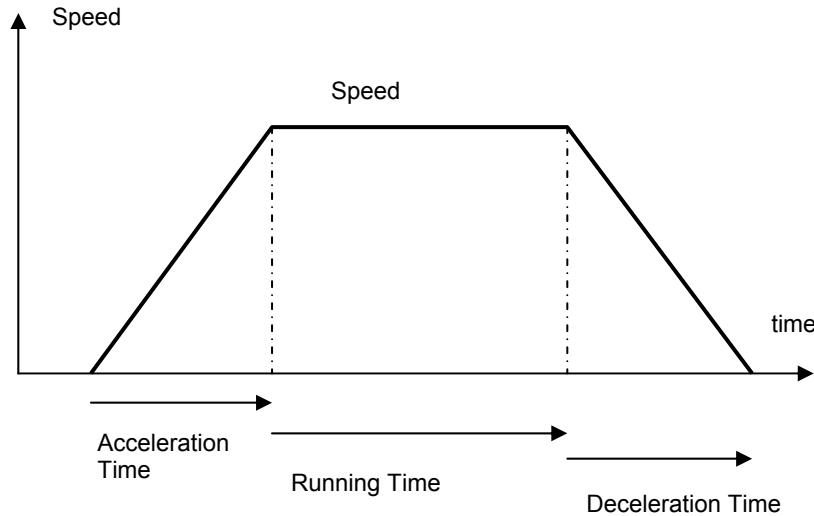

The Home sequence runs like in Homing Mode.

### Supported keywords and parameters for a home sequence

| Keyword       | Direct parameter entry | Description                                                                                     |
|---------------|------------------------|-------------------------------------------------------------------------------------------------|
| SeqType       | 0x3611-1               | value = HOME for SEQUENCE.TXT file or value = 2 for direct parameter object                     |
| NextSeq       | 0x3611-2               | see sequence parameters                                                                         |
| SeqCount      | 0x3611-3               | see sequence parameters                                                                         |
| SeqLink       | 0x3611-4               | see sequence parameters                                                                         |
| Trigger       | 0x3611-5               | see sequence parameters                                                                         |
| Output        | 0x3611-6               | see sequence parameters                                                                         |
|               | 0x3611-7               |                                                                                                 |
|               | 0x3611-8               |                                                                                                 |
| StartCond     | 0x3611-9               | see sequence parameters                                                                         |
|               | 0x3611-10              |                                                                                                 |
| Method        | 0x3611-22              | defines various ways of the drive to search the homing position                                 |
| Home offset   | 0x3611-13              | defines the position value when the motor reaches the homing position                           |
| Speed         | 0x3611-15              | defines the speed during search of switch (velocity unit)                                       |
| Speed2        | 0x3611-16              | defines the speed during search of zero (velocity unit)                                         |
| Accel         | 0x3611-19              | defines the acceleration time in acceleration unit                                              |
| Current Limit | 0x3611-25              | defines the current limit in per thousand of the rated current for a homing on mechanical limit |
| EndCond       | 0x3611-11              | see sequence parameters                                                                         |
|               | 0x3611-12              |                                                                                                 |

### **3.2.3.8.3 - Speed Sequence**

The speed sequence allows moving the axis with a profile speed as follows:

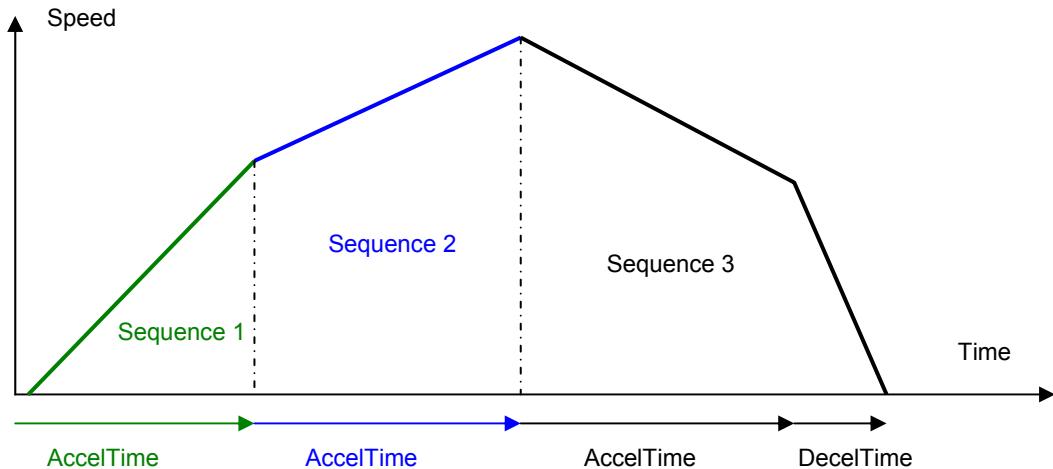

The main parameters of a speed sequence are:

- Speed setpoint
- Acceleration Time
- Deceleration Time
- Running Time

If the Running Time is 65535 (maximum of 16-bit) then the running phase will be executed forever. An "End Condition" can be used to exit this sequence.

If the deceleration Time is 0, then the sequence will end up after the running phase. This allows combining several sequences for a special profile.

Example of combined sequences:

Sequence 1:

```
SeqType = SPEED
Speed = 150000
AccelTime = 400
RunTime = 0
DecelTime = 0
NextSeq = 2
```

Sequence 2:

```
SeqType = SPEED
Speed = 250000
AccelTime = 400
RunTime = 0
DecelTime = 0
NextSeq = 3
```

Sequence 3:

```
SeqType = SPEED
Speed = 140000
RunTime = 0
AccelTime = 400
DecelTime = 150
```

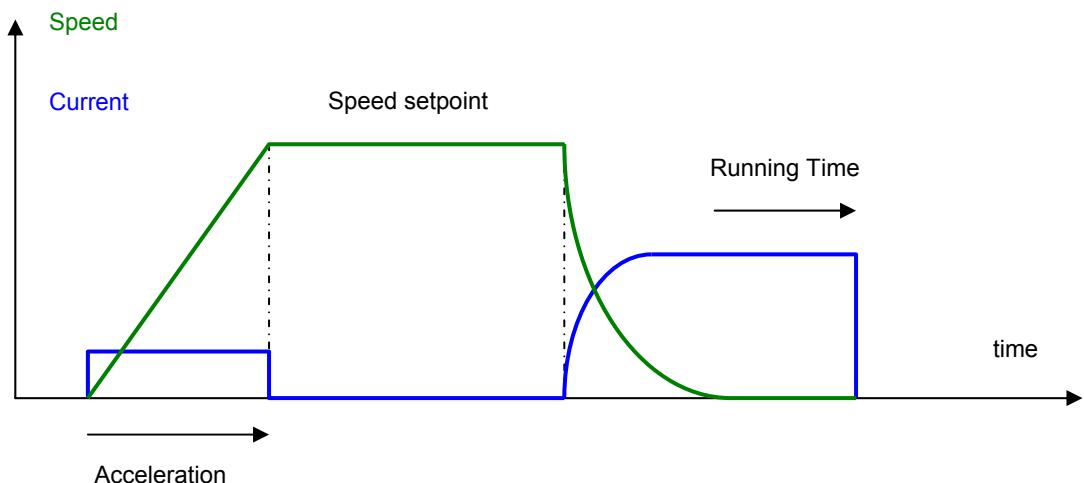

The speed setpoint of the Speed Sequence is also limited by the value of the Speed Modulation (0x3081). If the speed modulation is defined, then the sequence speed will be reduced by the speed modulation value.

### Supported keyword and parameters for a speed sequence

| Keyword   | Direct parameter entry | Description                                                                                  |
|-----------|------------------------|----------------------------------------------------------------------------------------------|
| SeqType   | 0x3611-1               | value = SPEED for SEQUENCE.TXT file or<br>value = 3 for direct parameter object              |
| NextSeq   | 0x3611-2               | see sequence parameters                                                                      |
| SeqCount  | 0x3611-3               | see sequence parameters                                                                      |
| SeqLink   | 0x3611-4               | see sequence parameters                                                                      |
| Trigger   | 0x3611-5               | see sequence parameters                                                                      |
| Output    | 0x3611-6               | see sequence parameters                                                                      |
|           | 0x3611-7               |                                                                                              |
|           | 0x3611-8               |                                                                                              |
| StartCond | 0x3611-9               | see sequence parameters                                                                      |
|           | 0x3611-10              |                                                                                              |
| Tempo     | 0x3611-23              | see sequence parameters                                                                      |
| Speed     | 0x3611-15              | defines the speed setpoint of this sequence in velocity unit                                 |
| AccelTime | 0x3611-19              | defines the acceleration time in ms.                                                         |
| DecelTime | 0x3611-20              | defines the deceleration time in ms.                                                         |
| RunTime   | 0x3611-24              | defines the running time in ms.<br>A value of 65535 corresponds to an infinite running time. |
| EndCond   | 0x3611-11              | see sequence parameters                                                                      |
|           | 0x3611-12              |                                                                                              |

#### 3.2.3.8.4 - Torque Sequence

The torque sequence allows moving the axis with a profile speed and a current limit.

The main parameters of a torque sequence are:

- Speed setpoint
- Acceleration
- Running Time
- Current limit (Torque Limit)

In the torque control sequence, the motor is running at the speed setpoint value until the current rises up to the limit value. The motor running direction depends on the sign of the speed setpoint. When the current limitation is reached, the amplifier is holding this current during the time interval defined by the Running Time parameter. If the Running Time = 65535, the torque holding time is infinite. In this case, the sequence can be left by an end condition.

At the end of the Running Time, the current position will be captured in object 0x360B.

#### Notes:

When Torque Sequence is executed, the position following error is disabled.

The Torque Sequence speed is also limited by the value of the Speed Modulation (0x3081). If the speed modulation is defined, then the sequence speed will be reduced by the speed modulation value.

### Supported keywords and parameters for a torque sequence

| Keyword   | Direct parameter entry | Description                                                                              |
|-----------|------------------------|------------------------------------------------------------------------------------------|
| SeqType   | 0x3611-1               | Value = TORQUE for SEQUENCE.TXT file or<br>Value = 4 for direct parameter object         |
| NextSeq   | 0x3611-2               | See sequence parameters                                                                  |
| SeqCount  | 0x3611-3               | See sequence parameters                                                                  |
| SeqLink   | 0x3611-4               | See sequence parameters                                                                  |
| Trigger   | 0x3611-5               | See sequence parameters                                                                  |

| EndCond   | 0x3611-11              | See sequence parameters                                                                  |
|           | 0x3611-12              |                                                                                          |

#### 3.2.3.8.5 - Gearing Sequence

The Gearing sequence is a sequence with gearbox function (see Gearbox Function for more information).

##### Gearing sequence parameters:

The main parameters for a gearing sequence are:

|                                  |                                                                                                                                                                                                                                               |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Config:</i>                   | Defines the gearing behaviour:<br>- Exit Mode<br>- Trigger Mode<br>- Start Mode<br>- Ratio Set Select<br>- Ratio Modulation Enable<br>This parameter is defined like in the gearbox configuration 0x3928,1                                    |
| <i>Factor:</i>                   | Defines the gearing ratio factor value                                                                                                                                                                                                        |
| <i>Acceleration:</i>             | Defines the acceleration value of the slave for acceleration phase, deceleration phase and slave phase shift adjustment.                                                                                                                      |
| <i>Differential speed:</i>       | Defines the differential speed for slave phase shift adjustment.                                                                                                                                                                              |
| <i>Master distance:</i>          | Defines the distance for the master from the start to the synchronization point.                                                                                                                                                              |
| <i>Slave distance:</i>           | Defines the distance for the slave from the start to the synchronization point.                                                                                                                                                               |
| <i>Synchronization distance:</i> | Defines the distance which the slave must be synchronized in position with.<br>If the synchronization distance is 0, then the slave will synchronize with the master indefinitely. A stop condition can be used to exit the gearing sequence. |

The master distance and the slave distance parameters must be adjusted so that the slave is synchronized before the synchronization point.

**Gearing global parameters:**

Beside parameters defined in a sequence, the gearing function has other global parameters which are not defined in the sequence and are applied to all gearing sequences.

|                                    |                                                                                                                                                       |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Master input:</i>               | Defines:<br>- master input source<br>- master start position<br>- hardware inputs for starting.                                                       |
| <i>Gearing ratio sets:</i>         | 2 sets of selectable gearing ratios (numerator and denominator) can be used                                                                           |
| <i>Gearing control:</i>            | Allows controlling a gearing sequence by an external source (i.e. via fieldbus or hardware input):<br>- ratio set select<br>- Slave Phase Shift start |
| <i>Slave Phase Shift Distance:</i> | Defines the Slave Phase Shift value for slave position adjustment.                                                                                    |

**Supported keyword and parameters for a gearing sequence in sequence file:**

| Keyword   | Direct parameter entry | Description                                                                                                |
|-----------|------------------------|------------------------------------------------------------------------------------------------------------|
| SeqType   | 0x3611-1               | value = GEAR for SEQUENCE.TXT file or<br>value = 5 for direct parameter object                             |
| NextSeq   | 0x3611-2               | see sequence parameters                                                                                    |
| SeqCount  | 0x3611-3               | see sequence parameters                                                                                    |
| SeqLink   | 0x3611-4               | see sequence parameters                                                                                    |
| Trigger   | 0x3611-5               | see sequence parameters                                                                                    |
| Output    | 0x3611-6               | see sequence parameters                                                                                    |
|           | 0x3611-7               |                                                                                                            |
|           | 0x3611-8               |                                                                                                            |
| StartCond | 0x3611-9               | see sequence parameters                                                                                    |
|           | 0x3611-10              |                                                                                                            |
| Tempo     | 0x3611-23              | see sequence parameters                                                                                    |
| Config    | 0x3611-21              | defines the gearing behaviour                                                                              |
| Factor    | 0x3611-26              | defines the gearing ratio factor                                                                           |
| Speed     | 0x3611-15              | defines the differential speed for the slave phase shift adjustment                                        |
| Accel     | 0x3611-19              | defines the acceleration value for acceleration phase, deceleration phase and slave phase shift adjustment |
| MasterDtn | 0x3611-13              | defines the master distance                                                                                |
| SlaveDtn  | 0x3611-14              | defines the slave distance                                                                                 |
| SyncDtn   | 0x3611-16              | defines the synchronization distance                                                                       |
| EndCond   | 0x3611-11              | see sequence parameters                                                                                    |
|           | 0x3611-12              |                                                                                                            |

**3.2.3.8.6 - Sequence Chaining**

The sequence chaining is controlled by 4 parameters:

- SeqCount,
- SeqNext,
- SeqLink,
- and StartCond.

"SeqCount" defines how many times this sequence will be executed. Then the sequencer will link to SeqNext if the counter is not 0 or link to SeqLink if the counter has expired.  
There must be only one SeqCount at a time.

"SeqNext" defines the sequence to be executed after the current one.

When a sequence is started:

If "StartCond" is defined:

If "start condition" is valid, then the sequence will be executed and then link "SeqNext"

If "Start condition" is not valid, then the sequence is not executed but jump to "SeqLink"

If "StartCond" is not defined:

the sequence will be executed and then link "SeqNext".

## COUNTER LOOP

The sequence linkage is controlled by the “SeqNext”, “SeqCount” and “SeqLink” parameters.

Application example:

Sequence 1:

```
SeqCount = 0
SeqNext = 2
SeqLink = -1
```

Sequence 2:

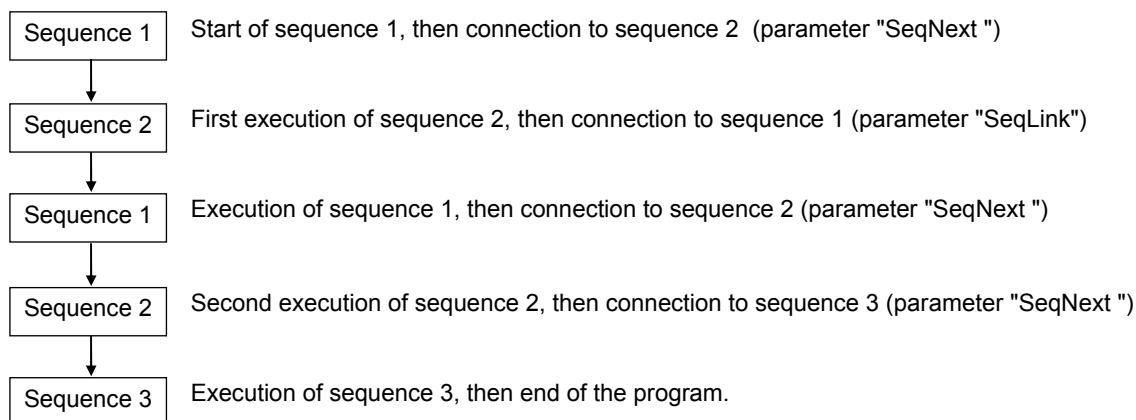

```
SeqCount = 2
SeqNext = 3
SeqLink = 1
```

Sequence 3:

```
SeqCount = 0
SeqNext = -1
SeqLink = -1
```

Note: SeqNext = -1 or SeqLink = -1 corresponds to an empty field in the Gem Drive Studio software.

If the execution is starting at sequence 1, the program will be the following:

## CONDITIONAL JUMP

The conditional jump is controlled by using the “StartCond” and the “SeqNext”, “SeqCount” and “SeqLink” parameters.

Application example:

Sequence 1:

```
SeqNext = 2
SeqCount = 0
SeqLink = -1
```

Sequence 2:

```
SeqNext = 3
SeqCount = 0
SeqLink = 4
Start Cond = "1....."
```

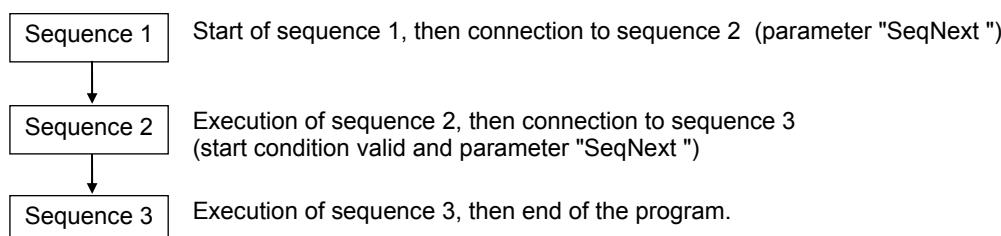

Sequence 3:

```
SeqNext = -1
SeqCount = 0
SeqLink = -1
```

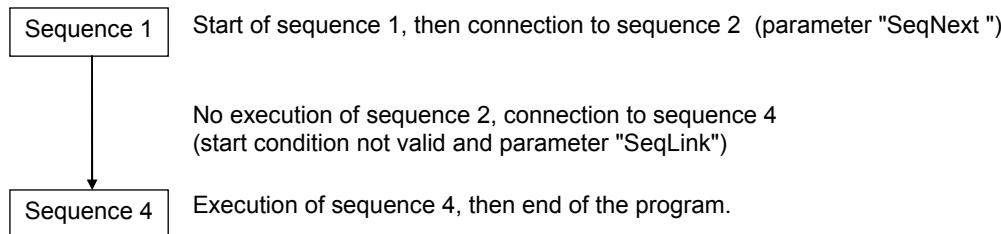

Sequence 4:

```
SeqNext = -1
SeqCount = 0
SeqLink = -1
```

If the execution is starting at sequence 1 and logic input 8 is activated, the program will be the following:

If the execution is starting at sequence 1 and logic input 8 is deactivated, the program will be the following:

### 3.2.3.8.7 - Sequence Parameters

#### Sequence Parameters

##### Supported keyword and parameters for all sequences

| Keyword   | Direct parameter entry           | Description                                                                                                                                                                 |
|-----------|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SeqNb     | 0x3610                           | Selects the sequence number (0..127)                                                                                                                                        |
| SeqType   | 0x3611-1                         | This parameter defines the sequence type:<br>POS (1)<br>HOME (2)<br>SPEED (3)<br>TORQUE (4)<br>GEAR (5)<br>in brackets is the value for direct parameter in object 0x3611-1 |
| NextSeq   | 0x3611-2                         | Defines the next sequence to be executed after this one if there is no condition or counter                                                                                 |
| SeqCount  | 0x3611-3                         | Defines how many times the sequence must be executed. This counter is decremented each time a sequence is over.                                                             |
| SeqLink   | 0x3611-4                         | Defines the number of the sequence to be executed when the SeqCount is not 0                                                                                                |
| Trigger   | 0x3611-5                         | Defines the output triggering event                                                                                                                                         |
| Output    | 0x3611-6<br>0x3611-7<br>0x3611-8 | Defines the output bit which will be reset<br>Defines the output bit which will be set<br>Defines the output bit which will be toggled                                      |
| StartCond | 0x3611-9<br>0x3611-10            | Defines the condition bit which starts the sequence when equal to 0<br>Defines the condition bit which starts the sequence when equal to 1                                  |
| Tempo     | 0x3611-23                        | Defines the delay time in ms at the end of the positioning                                                                                                                  |
| EndCond   | 0x3611-11<br>0x3611-12           | Defines the condition bit which stops the sequence when equal to 0<br>Defines the condition bit which stops the sequence when equal to 1                                    |

#### Sequence Inputs

|                    |                 |

| Number of Elements | 3               |

#### Value Description

|               |                       |
|---------------|-----------------------|
| Sub Index     | 1                     |
| Description   | Sequence Number Input |
| Data Type     | Integer16             |
| Object Class  | sq                    |
| Access        | rw                    |
| PDO Mapping   | Yes                   |
| Default Value | 0                     |

This object defines the sequence that will be executed when START is rising up.

|               |                          |
|---------------|--------------------------|
| Sub Index     | 2                        |
| Description   | Executed Sequence Number |
| Data Type     | Integer16                |
| Object Class  | sq                       |
| Access        | ro                       |
| PDO Mapping   | Yes                      |
| Default Value | -                        |

This object indicates the currently running sequence.  
A value of -1 means that no sequence is running.

|               |                   |
|---------------|-------------------|
| Sub Index     | 3                 |
| Description   | Conditional Input |
| Data Type     | Integer16         |
| Object Class  | sq                |
| Access        | rw                |
| PDO Mapping   | Yes               |
| Default Value | 0                 |

This object defines the bits pattern which is used for start condition or end condition.

| PDO Mapping  | Yes                        |

## Supported Sequence Types

Various sequence types can be implemented in a given firmware and drive model. This object shows supported sequence types. This object is read only.

| Index        | 0x360F                   |
|--------------|--------------------------|
| Name         | Supported sequence types |
| Object Code  | VAR                      |
| Data Type    | Unsigned16               |
| Object Class | sq                       |
| Access       | ro                       |
| PDO Mapping  | No                       |
| Value        | See below                |

## Data Description

| Bit Number | Function                       |
|------------|--------------------------------|
| 0          | Positioning sequence supported |
| 1          | Homing sequence supported      |
| 2          | Velocity sequence supported    |
| 3          | Torque sequence supported      |
| 4          | Gearbox sequence supported     |
| 5          | Cam sequence supported         |

## Maximum Sequences supported

This object gives the maximum sequences supported by a given device.  
The sequence number is between 0 and maximum sequences supported - 1

| Index        | 0x3612                     |
|--------------|----------------------------|
| Name         | Maximum sequence supported |
| Object Code  | VAR                        |
| Data Type    | Unsigned16                 |
| Object Class | sq                         |
| Access       | ro                         |
| PDO Mapping  | No                         |
| Value        | See below                  |

## Sequence Parameters Number

| Index         | 0x3610                     |
|---------------|----------------------------|
| Name          | Sequence Parameters Number |
| Object Code   | VAR                        |
| Data Type     | Integer16                  |
| Object Class  | sq                         |
| Access        | rw                         |
| PDO Mapping   | No                         |
| Default Value | 0                          |

This parameter holds the sequence number for direct reading/writing into sequence parameters by object 0x3611.

## Sequence Parameters

| Index              | 0x3611              |
|--------------------|---------------------|
| Name               | Sequence Parameters |
| Object Code        | RECORD              |
| Number of Elements | 26                  |

This object allows reading/writing all parameters of a sequence which number is given in object 0x3610.

## Value Description

|               |               |
|---------------|---------------|
| Sub Index     | 1             |
| Description   | Sequence Type |
| Data Type     | Integer16     |
| Object Class  | sq            |
| Access        | rw            |
| PDO Mapping   | No            |
| Default Value |               |

This parameter allows reading/writing the type of a sequence. Check object 0x360F for supported sequence types.

The value is the sequence type:

| Value | Function                           |
|-------|------------------------------------|
| 0     | Not defined                        |
| 1     | Positioning sequence               |
| 2     | Homing sequence                    |
| 3     | Speed sequence                     |
| 4     | Torque sequence                    |
| 5     | Gear sequence (if device supports) |
| 6     | Cam sequence (if device supports)  |

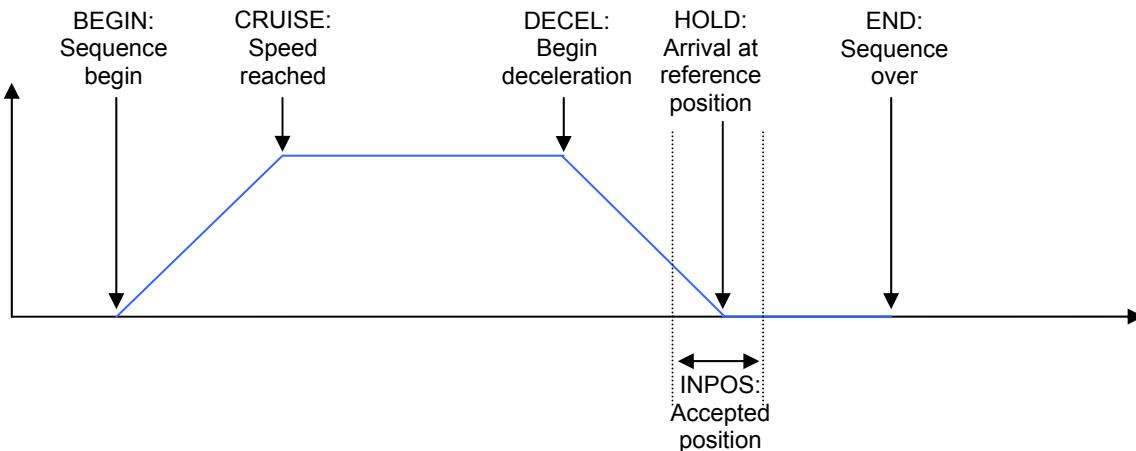

|               |                                                |
|---------------|------------------------------------------------|

| Unit          | ms                |
| Value Range   | 0..65535          |
| Default Value | 0                 |

|               |               |
|---------------|---------------|
| Sub Index     | 21            |
| Description   | Configuration |
| Data Type     | Unsigned16    |
| Object Class  | sq            |
| Access        | rw            |
| PDO Mapping   | No            |
| Default Value | 0             |

For a position sequence, this parameter defines the positioning type:

| Value | Function             |
|-------|----------------------|
| 0     | Absolute positioning |
| 1     | Relative positioning |

For a homing sequence, this parameter defines the "return" configuration:

| Value | Function                  |
|-------|---------------------------|
| 0     | No return                 |
| 1     | Return to homing position |

|               |                 |
|---------------|-----------------|
| Sub Index     | 22              |
| Description   | Configuration 2 |
| Data Type     | Integer16       |
| Object Class  | sq              |
| Access        | rw              |
| PDO Mapping   | No              |
| Default Value | 0               |

For a homing sequence, this parameter defines the homing method.

|               |               |
|---------------|---------------|
| Sub Index     | 23            |
| Description   | Temporization |
| Data Type     | Unsigned16    |
| Object Class  | sq            |
| Access        | rw            |
| PDO Mapping   | No            |
| Unit          | ms            |
| Value Range   | 0...16000     |
| Default Value | 0             |

|               |              |
|---------------|--------------|
| Sub Index     | 24           |
| Description   | Running Time |
| Data Type     | Unsigned16   |
| Object Class  | sq           |
| Access        | rw           |
| PDO Mapping   | No           |
| Unit          | ms           |
| Value Range   |              |
| Default Value | 0            |

For a speed sequence or a torque sequence, if the Running Time is 65535 (maximum of 16-bit), then the running phase will be executed forever. An "End Condition" can be used to exit this sequence.

|               |                     |
|---------------|---------------------|
| Sub Index     | 25                  |
| Description   | Analog In           |
| Data Type     | Integer16           |
| Object Class  | sq                  |
| Access        | rw                  |
| PDO Mapping   | No                  |
| Unit          | 16-bit scaled value |
| Value Range   |                     |
| Default Value | 0                   |

For a torque sequence, this parameter defines the torque value.

For a homing sequence, this parameter defines the home current limit value.

|               |                                      |

| Access        | rw                                   |
| PDO Mapping   | No                                   |
| Unit          | 16-bit scaled value                  |
| Value Range   |                                      |
| Default Value | 0                                    |

### 3.2.3.8.8 - Sequence File Format

#### Description

1. Sequence files are text files.  
Characters are not case sensitive.
2. The parameter syntax is:  
Key\_word = value  
There must be only one key word per line.
3. The parameter value can be:
  - a number: decimal or hexadecimal (preceded by 0x)
  - a constant (text)
4. The character ; indicates the begin of a comment to the end of the line.
5. A sequence begins with keyword **SeqNb**
6. The parameters of a sequence are declared one after the other. Except for **SeqNb**, the parameter order has no importance.
7. There is no indication for the end of a sequence. A new sequence with SeqNb indicates the end of the current sequence.

8. Incoherent parameters or values out of the limits will generate an error.
9. In a sequence, parameters which are not declared will have a default value.  
The default value can be changed by means of the **Default** keyword.
10. The sequencer can load sequence files in two ways:
  - LOAD: load declared sequences from the sequence file into memory. Sequences that are not declared will be cleared.
  - MERGE: load declared sequences from the sequence file into memory. Sequences that are not declared in the file will be kept.

#### **Sequence file example:**

```

; define some default values
Default
Accel=100000
Decel=100000

; sequence 1: positioning
SeqNb=1
SeqType=pos
Pos=0x001000
PosType=ABS           ; absolute positioning
Speed=100000
Output=".001000"
Trigger=begin ; activate outputs at the beginning of the sequence
Tempo=1000
SeqNext=3

; sequence 3: run at high speed during 10 s
SeqNb=3
SeqType=speed
AccelTime=200000
DecelTime=200000
Speed=500000
RunTime=10000

```

#### **Sequence Keyword**

Supported sequence types:

- Positioning sequence
- Homing sequence
- Speed sequence
- Torque sequence

#### **General Parameters**

General parameters are for all sequence types.

| <b>Key word</b> | <b>Signification/Constance</b>                    |
|-----------------|---------------------------------------------------|
| SeqType         | Sequence Type<br>POS, SPEED, HOME, TORQUE, GEAR   |
| SeqNext         | Next sequence                                     |
| SeqCount        | Sequence Counter                                  |
| SeqLink         | Conditional Jump                                  |
| Output          | Output                                            |
| Trigger         | Output trigger<br>BEGIN, CRUISE, DECEL, HOLD, END |

| Decel           | Deceleration         |
| RunTime         | Torque limit Time    |
| Torque          | Torque limit         |

**3.2.3.9 - Stepper Emulation Mode****Stepper Emulation Mode**

The Stepper emulation mode emulates the behaviour of a stepper motor and drive.

The position reference is given by the PULSE and DIR inputs: when pulse following control is enabled in the control word, the servo motor position setpoint is received via the PULSE and DIR input pins.

The stepper motor emulation application is only possible for motors equipped with a resolver as a position feedback sensor. The encoder input is used for pulse/dir command input (the encoder input must be selected with incremental TTL encoder).

When the drive is switched on with the stepper emulation mode selected, Pulse following control is disabled. In this case, the input pulses are not counted and the motor is enabled at standstill.

The motor starts following the input pulses when PULSE\_ENA (control word bit 4) is set or COUNT\_ENA (0x3681-3 bit 8) is set.

The specific bits of the control word (object 0x6040) used in stepper emulation mode are described below:

| <b>Bit</b> | <b>Name</b> | <b>Function</b>        |
|------------|-------------|------------------------|
| 4          | PULSE_ENA   | Enable pulse following |
| 5          |             | Reserved               |
| 6          |             | Reserved               |

The specific bits of the status word (object 0x6041) used in stepper emulation mode are described below:

| Bit | Name      | Function           |
|-----|-----------|--------------------|
| 12  | PULSE_OK  | Pulse following ok |
| 13  | PULSE_CNT | Pulse Count        |

The PULSE\_OK is set when drive is enabled and PULSE\_ENA or COUNT\_ENA is set.  
The PULSE\_CNT is active only with PULSE\_OK active. The PULSE\_CNT signal is described in object 0x3681.

The motor Maximum speed value is calculated according to the host controller pulse frequency limit as follows:  
Maximum speed (rpm) = 60 x pulse frequency limit (Hz) / Stepper resolution.

For simple count configuration (object 0x3681-3 bit 7 = 0), the Stepper resolution = User position scaling (object 0x6093-2).

For double count configuration (object 0x3681-3 bit 7 = 1), the Stepper resolution = User position scaling (object 0x6093-2) / 2.

The Max. Motor Speed parameter (object 0x6080) is set to the previously calculated maximum speed value + 10 % to avoid a speed saturation of the drive.

The motor speed depends on the pulse frequency and the User position scaling parameter (object 0x6093-2).

The motor displacement direction with regard to the DIR input logic state can be configured by using the reverse bit of the resolver input.

The polarity of the PULSE and DIR inputs is configurable by 0x3681.

Object 0x392C,0 gives the input pulse counter value.

Object 0x3685,0 gives the stepper emulation reference value.

If the drive is disabled or if the drive is enabled and PULSE\_ENA and COUNT\_ENA are at 0, then this object is cleared.

Object 0x3686,0 gives the position setpoint applied to the drive position loop.

### Object Dictionary Entries

| Index  | Object | Name                                   | Type      | Attr. |
|--------|--------|----------------------------------------|-----------|-------|
| 0x3681 | VAR    | Stepper Emulation Configuration        | ARRAY     | rw    |

| PDO Mapping     | No                                                                                                                                                        |
| Unit            | Hz                                                                                                                                                        |
| Possible values | 200, 100, 40, 20                                                                                                                                          |
| Default Value   | 40                                                                                                                                                        |
| Remark          | Stepper input filter proportional gain (0x3681,5) and integral gain (0x3681,6) are automatically calculated according to the cut-off frequency selection. |

## Example of Stepper Emulation Configuration

### 1. Selection of the Stepper Emulation Mode

- Mode of operation 0x6060,0 = -2 (this can be done in Gem Drive Studio)

### 2. Activate PULSE/DIR inputs:

- Enable the TTL incremental encoder input
- Disable the encoder error control: 0x3025,1 = 0x00240000
- Setup the PULSE/DIR with 0x3681,3 = 0x013A (Inputs from Hall Effect Sensor lines on the encoder connector)
- Set the User position scaling parameter (0x6093-2) according to the desired motor speed  
Motor Speed (rpm)=60 \* Pulse\_Frequency / User position scaling (0x6093-2) for simple count selection  
Motor Speed (rpm)=120 \* Pulse\_Frequency / User position scaling (0x6093-2) for double count selection

### 3. Setup the PULSE\_CNT output:

- PULSE\_CNT timing: 0x3681,4 = 10
- Connect PULSE\_CNT signal to logic output OUT3  
0x3504,3 = 0x36810201 (this can be done in Gem Drive Studio)

### 4. The auto-tuning must be executed with "minimum position overshoot".

After the auto-tuning, the Kav Feedforward acceleration Gain term (0x60FB,4) must be reset at 0.

### **3.2.3.10 - Analog Speed Mode**

#### Analog Speed Mode

In this mode, the ServoPac TT drive operates as a variable speed drive.

The speed reference is the analog input 1.

The maximum speed defined by 0x6080 is reached with 10 V input.

The acceleration time from 0 to maximum speed and the deceleration time from maximum speed to 0 are defined in ms by object 0x604F.

The deceleration time is also defined in ms by object 0x304F. This allows setting a deceleration time different from the acceleration time.

Operation Mode number: -1 (0x6060)

If HALT bit in control word (0x6040) is set, the speed reference is reset at 0.

| Index         | 0x604F        |
|---------------|---------------|
| Name          | Velocity Ramp |
| Object Code   | VAR           |
| Data Type     | Unsigned32    |
| Object Class  | as            |
| Access        | rw            |
| PDO Mapping   | No            |
| Unit          | ms            |
| Value Range   | 0 - 0x3FFF80  |
| Default Value | 0             |

This object defines the acceleration time from 0 to maximum motor speed defined in 0x6080, and the deceleration time from maximum motor speed to 0.

| Index         | 0x304F          |
|---------------|-----------------|
| Name          | Velocity Ramp 2 |
| Object Code   | VAR             |
| Data Type     | Unsigned32      |
| Object Class  | as              |
| Access        | rw              |
| PDO Mapping   | No              |
| Unit          | ms              |
| Value Range   | 0 - 0x3FFF80    |
| Default Value | 0               |

This object defines the deceleration time from maximum motor speed to 0.

### 3.2.3.11 - Analog Torque Mode

#### Analog Torque Mode

In this mode, the ServoPac TT drive operates in current loop with current reference from analog input 1.

The Analog Input value is given by:

$$\text{Analog\_Input\_1} = (\text{ADC} - \text{AnalogIn1Offset}) * \text{AnalogIn1Gain} / 256$$

ADC value = 0x7FF0 for 10 V

AnalogIn1Offset is the offset of the analog input and is defined by object 0x30F1,3

AnalogIn1Gain is defined by object 0x30F1,4

The current reference is set with Analog\_Input\_1. A value of 0x7FFF corresponds to drive size (0x6510,1)

If HALT bit in control word (0x6040) is set, then the current reference is reset at 0.

The object 0x3077,0 allows defining a window in which the status bit Target\_Reached is set.

Analog torque operation mode selection code: -5 (0x6060)

| Index         | 0x3077                         |

| Unit          | 0x7FFF -> drive current rating |
| Default Value | 0                              |

### 3.2.3.12 - Gearing Mode

The gearbox mode is an operation mode which supports gearbox function. The main gearbox control takes effect with the operation mode specific bits in control word (0x6040) and main gearbox indicators are in operation mode specific bits of status word (0x6041).

Mode of Operation: -6

Control Word (0x6040):

| Bit | Action                                |
|-----|---------------------------------------|
| 4   | 1 Gearbox Enable<br>0 Gearbox disable |
| 5   | ↑ Start Slave Phase Shift Adjustment  |
| 12  | ↑ Start Master Phase Shift Adjustment |

Status Word (0x6041):

| Bit | Action          |
|-----|-----------------|
| 10  | InGear          |
| 12  | Gearbox running |
| 13  |                 |

Gearbox mode parameters:

|                                          |                                                                                                                                                                                                                                                                                                  |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| config:<br>0x3928,1                      | Defines the gearing behaviour:<br>- Exit Mode<br>- Trigger Mode<br>- Start Mode<br>- Ratio Set Select<br>- Ratio Modulation Enable                                                                                                                                                               |

| acceleration:<br>0x392A,0                | Defines the acceleration value of the slave for the acceleration phase, deceleration phase and adjustment phase.                                                                                                                                                                                 |
| speed:<br>0x392C,0                       | Defines the relative speed for the slave phase shift adjustment.                                                                                                                                                                                                                                 |
| master distance:<br>0x3925,1             | Defines the distance of the master from the start to the synchronization point.                                                                                                                                                                                                                  |
| slave distance:<br>0x3925,2              | Defines the distance of the slave from the start to the synchronization point.<br>If the slave distance is 0, then the adjustment is not executed.<br>The master distance and the slave distance parameters must be adjusted so that the slave is synchronized before the synchronization point. |
| synchronization<br>distance:<br>0x3925,3 | Defines the distance of the slave so that the slave must be synchronized in position.<br>If the synchronization distance is 0, then the slave will indefinitely synchronize with the master. A stop condition can be used to exit the gearing sequence.                                          |

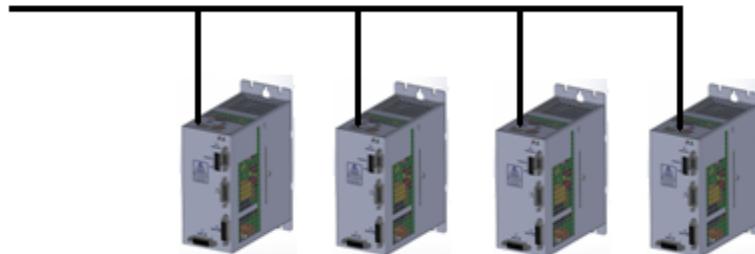

### 3.2.4 - MASTER-SLAVE FUNCTIONS

#### 3.2.4.1 - Master-Slave

ServoPac TT drives support master-slave relationship in which several drives run as a slave following a master. One drive can be used as a master and the master position reference can be distributed to all other drives via encoder output or CAN bus (EtherCAT® cannot be used without an EtherCAT® master).

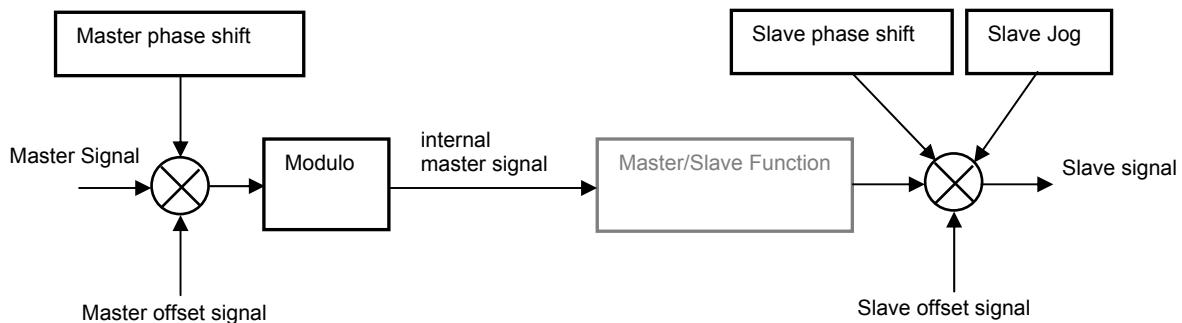

A virtual master signal can be generated by a drive and distributed to all other drives via CAN bus including the one with virtual master (which runs as a slave).

Input Signal -> Master

#### Master-Slave Function

In each drive running as a slave, a master input function block allows defining the master input source, offset and eventually apply a modulo operation on the master signal. The result signal "Internal Master Signal" is applied to the master-slave function block.

The Master Signal is a continue signal which can be connected to an internal signal or external signal.  
The Master Signal source can be defined by the source index/sub-index.

For example:

- Encoder signal from encoder input with a true encoder or an encoder emulation output from another drive.
- Signal from fieldbus master or from another drive (via CAN bus).
- Internal virtual master.

The "Internal Master Signal" is used as master position for all master/slave functions of the drive.

The master offset signal is a continuous signal which can be locally added to the master signal in each drive.  
The master offset signal can be linked to an internal or external signal (master offset source).  
The master offset source can be defined by its index/sub-index.

The master phase shift is a trapezoidal movement locally added to master signal in each drive.  
The master phase shift is defined with acceleration, speed, and master distance for phase shift.

The slave signal is the output signal that will be applied to the position loop of each drive.

The slave offset signal is a continuous signal which can be added to master/slave function output.  
The slave offset signal can be linked to an internal or external signal (slave offset source).  
The slave offset source can be defined by its index/sub-index.

The slave phase shift is a trapezoidal movement added to the master/slave function output. The slave phase shift is defined with acceleration, speed, and slave distance for phase shift.

The master phase shift command and slave phase shift command cannot be activated at the same time.

### Starting Master-Slave Operation

Master length allows applying a modulo operation on the master input signal. If master length = 0 then modulo operation is disabled.

If the master-slave function is a cam, the master length must be different from 0.

Trigger Mode: defines how to start the slave operation.

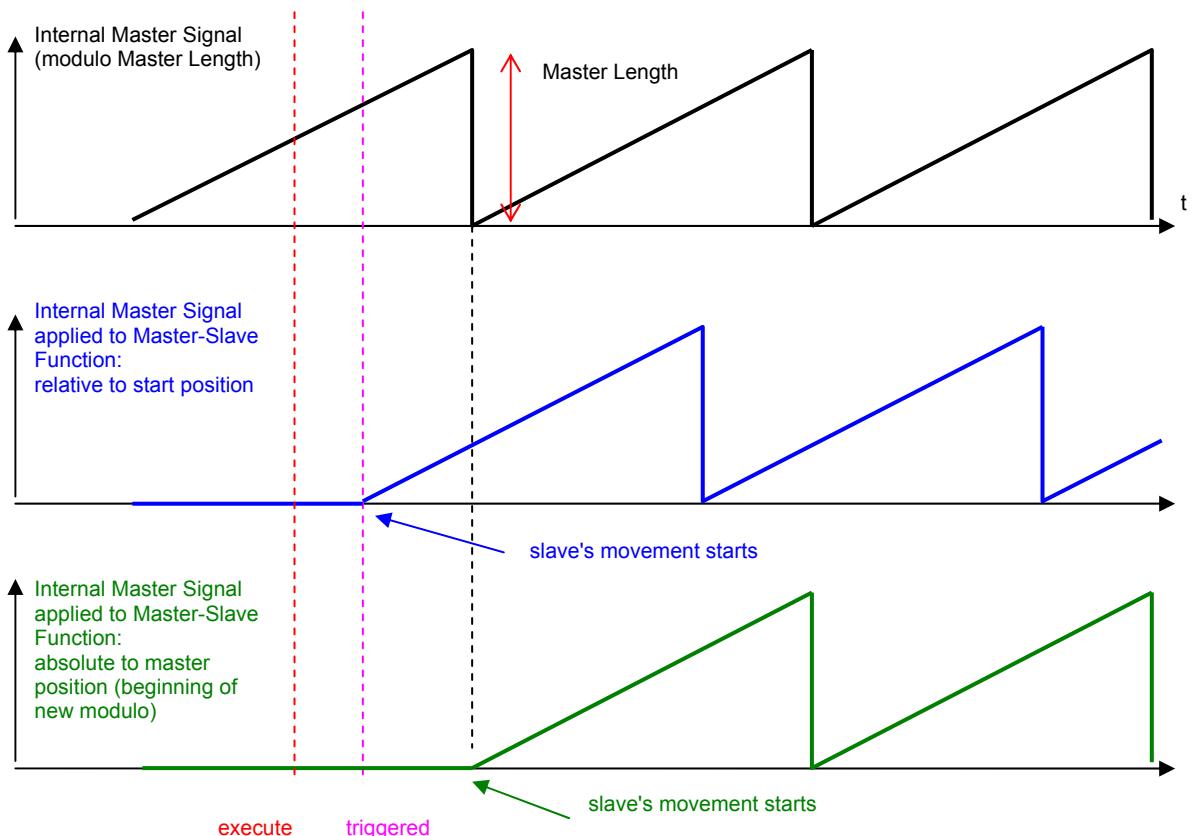

When the master-slave function is executed, the slave's movement can be triggered:

- immediately as soon as the master-slave function is executed,
- with rising edge on logic inputs

Start Mode: defines where to start the slave's movement.

When the slave is triggered, the slave's movement is started with the master position:

- relative to the start position or
- absolute to the master position (only with modulo).

Note: The scheme above shows a master running at constant speed.

## Master-Slave supported Functions

Depending on the device model, the supported master-slave functions are:

- Master-Slave gearbox
- Master-Slave cam

## Master-Slave Objects Definition

| Index  | Object | Name                                  | Type       | Attr. |

| Description   | Index/sub-index of input data |
| Data Type     | Unsigned32                    |
| Class         | sq gb cm                      |
| Access        | rw                            |
| PDO Mapping   | No                            |
| Value         | See below                     |
| Default Value | 0                             |

This object allows connecting any 32-bits dataflow as master input signal.

The master signal must be a 32-bit signal.

A modulo function will be applied to this signal. The result is given in 0x3916,0 which will be used for master slave function.

The structure of the entries is the following:

| MSB | Index (16-bit) | Sub-index (8-bit) | LSB |
|-----|----------------|-------------------|-----|
|     |                | 0                 |     |

### Example:

0x3910,0 = 0x31290000

connects the encoder Input as master input signal.

0x3910,0 = 0x39060000

connects the virtual master as master input signal.

0x3910,0 = 0x30C10000

connects the interpolated signal from CAN bus as master input signal.

| Name          | Master Offset Signal                                                 |
| Description   | This signal is added to the master signal for master slave function. |
| Data Type     | Integer32                                                            |
| Class         | sq gb cm                                                             |
| Access        | rw                                                                   |
| PDO Mapping   | Yes                                                                  |
| Value         | -                                                                    |
| Default Value | -                                                                    |

### Master Offset Source

|               |                                  |
|---------------|----------------------------------|
| <b>Index</b>  | <b>0x3913</b>                    |
| Name          | Master Offset Source             |
| Description   | Index/sub-index of offset signal |
| Data Type     | Unsigned32                       |
| Class         | sq gb cm                         |
| Access        | Rw                               |
| PDO Mapping   | No                               |
| Value         | See below                        |
| Default Value | 0                                |

This object allows connecting any 32-bit dataflow as master offset signal.

The master signal must be a 32-bit signal.

The structure of the entries is the following:

|                |                     |
|----------------|---------------------|
| MSB            | LSB                 |
| Index (16-bit) | Sub-index (8-bit) 0 |

#### Example:

0x3913,0 = 0x30F20200

connects the second analog input to the master offset signal (the analog signal will be copied into object 0x3912,0).

| Default Value | 0                           |

This object defines the bit pattern of the logic inputs that will trigger the master-slave functions.  
Each bit (0..15) corresponds to a logic input in 0x60FD,0 (bit 16..31).

|---------------|------------------------|
| Name          | Slave Acceleration     |
| Object Code   | VAR                    |
| Data Type     | Unsigned32             |
| Object Class  | gb cm sq               |
| Access        | rw                     |
| PDO Mapping   | No                     |
| Unit          | User acceleration unit |
| Value Range   | -                      |
| Default Value | -                      |

This object defines the acceleration used in master-slave functions:

- when the slave accelerates to catch-up the master's speed (gearbox),
- when the slave phase shift is activated.

| Index         | 0x392C                   |

| Default Value | -                                                                                                                                                                                                        |

| <b>Index</b>  | <b>0x3943</b> |
|---------------|---------------|
| Name          | Slave Offset  |
| Object Code   | VAR           |
| Data Type     | Integer32     |
| Object Class  | gb sq cm      |
| Access        | rw            |
| PDO Mapping   | No            |
| Unit          | Position unit |
| Default Value | 0             |

This object defines the position offset value added to the slave output.

### Slave Offset Source

| <b>Index</b>  | <b>0x3944</b>                 |
|---------------|-------------------------------|
| Name          | Slave Offset Source           |
| Description   | Index/sub-index of input data |
| Data Type     | Unsigned32                    |
| Class         | sq, gb, cm                    |
| Access        | rw                            |
| PDO Mapping   | No                            |
| Value         | See below                     |
| Default Value | 0                             |

This object allows connecting any 32-bit dataflow as slave offset signal.  
The value from the source signal will be copied into the slave offset signal (0x3943,0).

The structure of the entries is the following:

| MSB            | Sub-index (8-bit) | LSB |
|----------------|-------------------|-----|
| Index (16-bit) | 0                 |     |

Example:

0x3944,0 = 0x30F20200

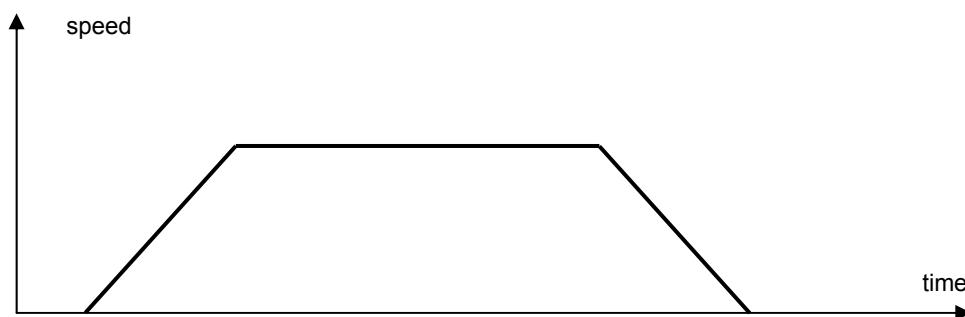

connects the Analog input 2 to the slave offset signal.

If this object is cleared, then the slave offset value is given from object 0x3943,0.

### 3.2.4.2 - Virtual Master

#### Virtual Master

Virtual master allows generating a position signal with a profile as shown below:

The profile starts as soon as the Virtual Master Speed is set with the defined acceleration, and the master signal slows down and stops when Virtual Master Speed is reset at 0. The virtual master output object can be used as master-slave input signal or distributed over CAN bus via PDO.

#### Virtual Master Objects Definition

| Index  | Object | Name                        | Type       | Attr. |
|--------|--------|-----------------------------|------------|-------|
| 0x3901 | VAR    | Virtual Master Speed Source | Unsigned32 | rw    |
| 0x3902 | VAR    | Virtual Master Speed        | Integer32  | rw    |
| 0x3903 | VAR    | Virtual Master Acceleration | Integer32  | rw    |
| 0x3906 | VAR    | Virtual Master Output       | Integer32  | rw    |

#### Virtual Master Speed Source

|               |                               |
|---------------|-------------------------------|
| Index         | 0x3901                        |
| Name          | Virtual Master Speed Source   |
| Description   | Index/sub-index of input data |
| Data Type     | Unsigned32                    |
| Class         | sq, gb, cm                    |
| Access        | rw                            |
| PDO Mapping   | No                            |
| Value         | See below                     |
| Default Value | 0                             |

This object allows connecting any 32-bit dataflow as virtual master speed signal. The content of the virtual master speed (0x3902,1) will be replaced by the content of the source.

The structure of the entries is the following:

| MSB            | LSB                   |
|----------------|-----------------------|
| Index (16-bit) | Sub-index (8-bit)   0 |

Example:

0x3901,0 = 0x30F10200

connects analog input 1 (32-bit format) to the virtual master speed input (0x3902,0).

| Index         | 0x3902                                                             |
|---------------|--------------------------------------------------------------------|
| Name          | Virtual Master Speed<br>defines the target for the virtual master. |

| Unit          | position unit         |
| Default Value | -                     |

This object gives the output value of the virtual master. This value:

- can be applied directly to master-slave functions or
- sent to other drives via the CAN bus. In this case, the virtual master output must also be sent to this drive itself via the CAN bus to avoid delay between this drive and all other drives.

### 3.2.4.3 - Gearbox Function

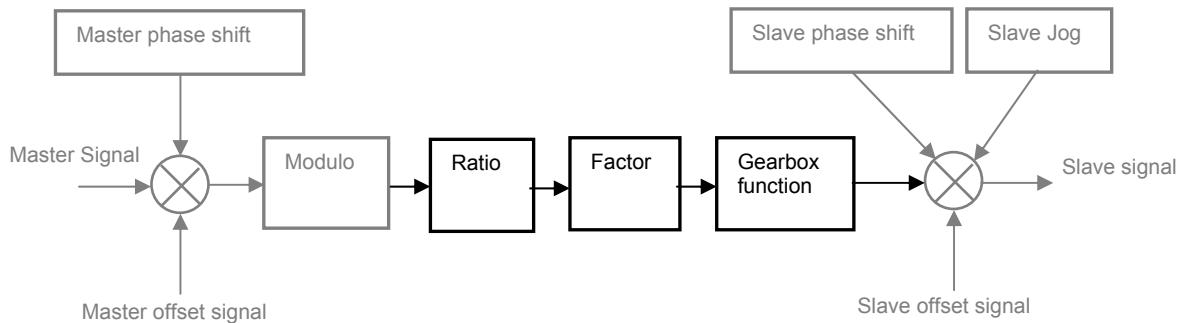

The ServoPac TT drive's gearbox function allows synchronizing the slave movement with a master signal in a relationship defined by a ratio:

$$\text{Slave\_Pos} = \text{Numerator}/\text{Denominator} * \text{Master\_Pos} + \text{Offset}$$

The gearbox function can be used:

- in a specific operation mode (manufacturer operation mode)
- or as a sequence inside the sequencer mode.

#### Structure of the Gearbox

When the gearbox function starts, the slave ramps up to the ratio of the master speed according to the gearing ratio value, and locks in when this is done. An adjustment on the slave's movement allows adjusting the motor position. When the adjustment is over, the motor position is locked in frequency and phase with the master position according to the gearing ratio value.

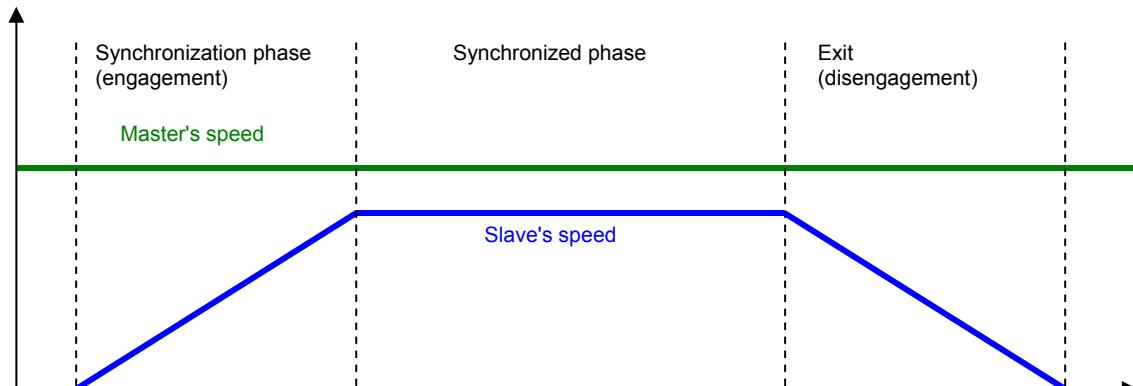

The Gearing ratio is defined by a numerator / denominator.

During a gearing sequence execution, this value can be multiplied by the sequence gearing ratio factor.

In gearing mode, when the gearbox function is not active, a jog input can be used to manually move the slave.

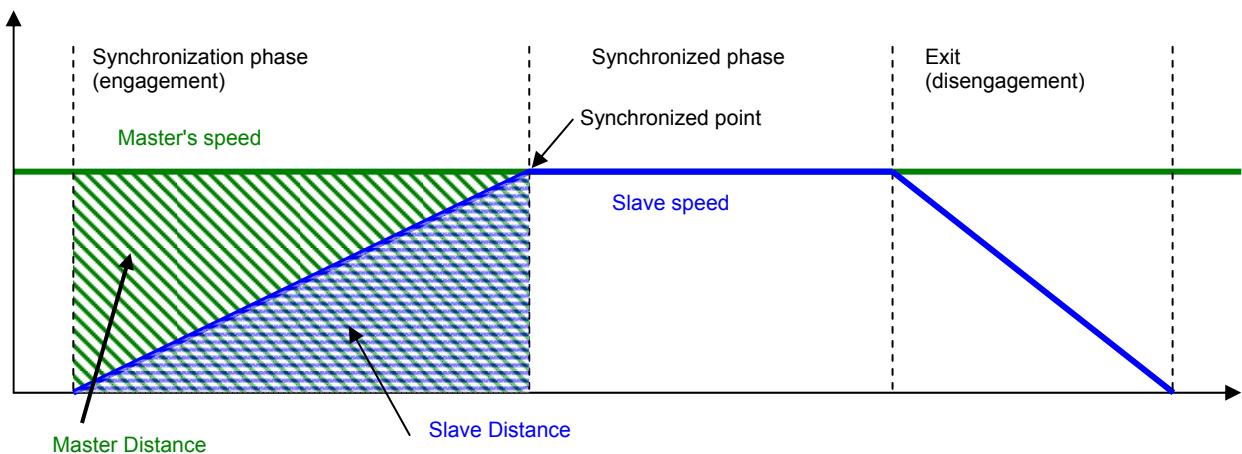

#### Coupling Mode

##### 1. Constant acceleration

The slave ramps up to the ratio of the master velocity and locks in when the master's speed is reached. Any lost distance during synchronization is not caught up.

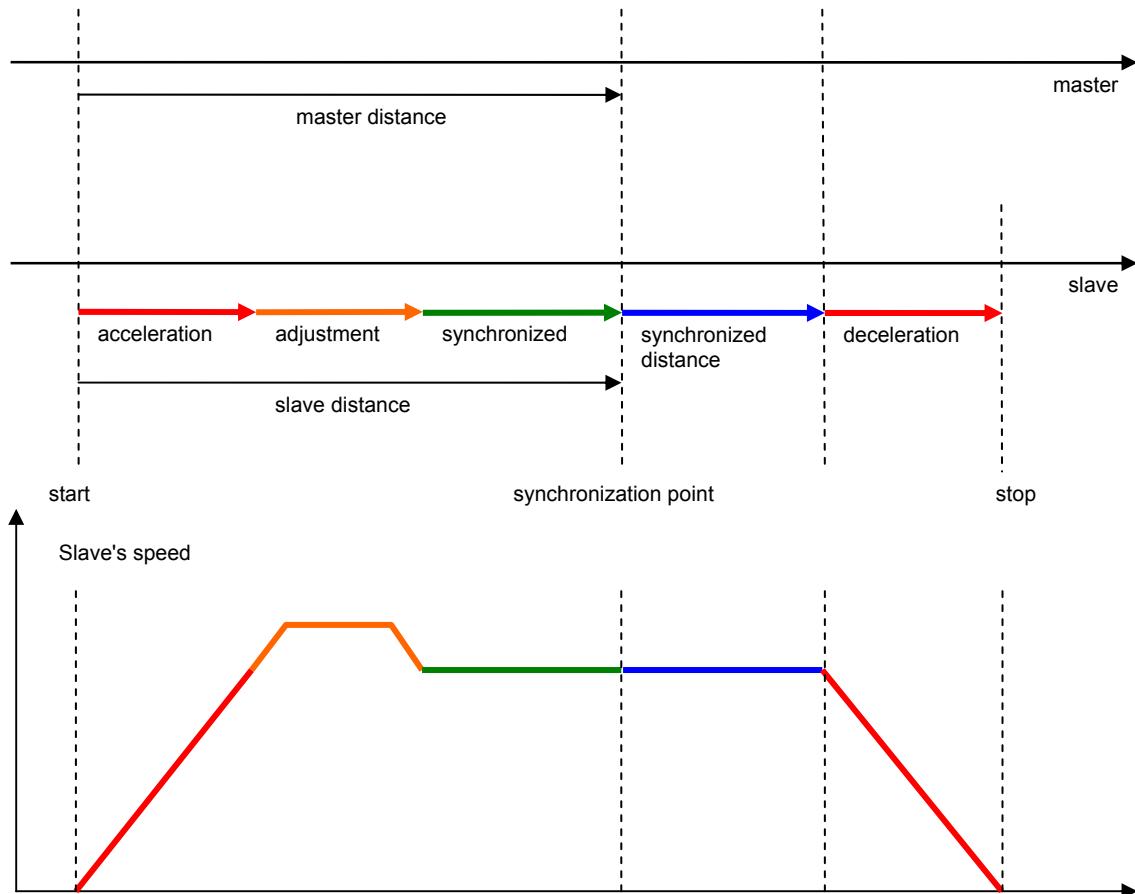

## 2. Constant Distance

In this coupling mode, the slave accelerates to reach the master's speed in order, for the slave, at the synchronized point, to have moved "slave distance" and for the master to have moved "master distance". So, if the master changes speed during acceleration phase, the slave speed will change as well. This coupling mode is for a master-slave ratio = 1, and the master distance = 2 x slave distance.

## 3. Constant acceleration with phase correction

In this coupling mode, the slave will accelerate at constant acceleration to reach the ratio of the master's speed and then a slave phase shift adjustment will be automatically performed to adjust the slave phase to the master phase with a parameter defined in Master Distance and Slave Distance.

After adjustment, the slave is synchronized with the master in the same phase. The master distance and slave distance must be defined so that the slave is synchronized before the synchronization point.

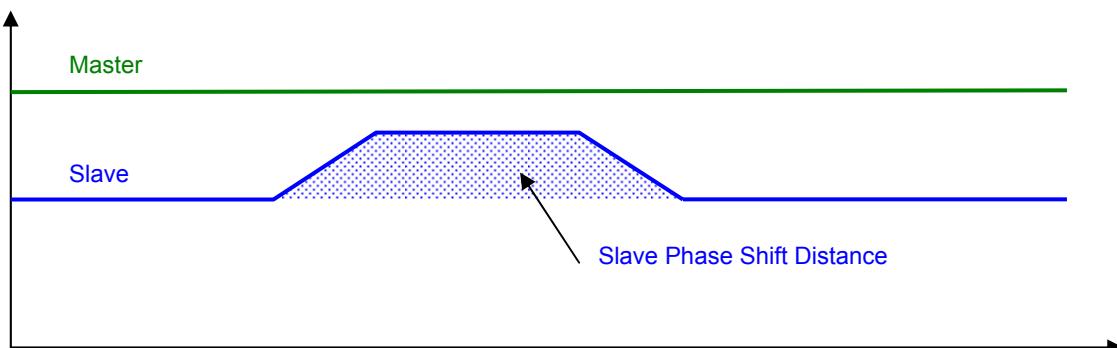

### Gearbox function parameters:

|                                 |                                                                                                                                                                                                                                                   |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Master input</i>             | Defines the master input source: encoder input, fieldbus signal.                                                                                                                                                                                  |
| <i>Ratio select</i>             | 2 sets of gearing ratios (numerator and denominator) can be pre-defined.<br>Ratio Select allows selecting the desired ratio set.<br>Ratio selection and ratio value can be modified on-the-fly.                                                   |
| <i>Ratio factor</i>             | A ratio factor (scaling factor) can also be applied for a continuously modified ratio                                                                                                                                                             |
| <i>Accel / decel</i>            | Defines acceleration/deceleration values for slave ramp up/down.                                                                                                                                                                                  |
| <i>Differential speed</i>       | Defines the relative speed for adjustment phase.                                                                                                                                                                                                  |
| <i>Master distance</i>          | Defines the distance for the master from the start to the synchronization point.                                                                                                                                                                  |
| <i>Slave distance</i>           | Defines the distance for the slave from the start to the synchronization point.<br>If the slave distance is 0, then adjustment is not executed.                                                                                                   |
| <i>Synchronization distance</i> | Defines the distance for the slave that the slave must be synchronized in position. If the synchronization distance is 0, then the slave will synchronize with the master indefinitely. An exit command can be used to exit the gearing function. |
| <i>Trigger Mode</i>             | - immediately executed command<br>- rising edge of a logic input                                                                                                                                                                                  |
| <i>Start Mode</i>               | - relative to initial position<br>- absolute to master position (modulo)                                                                                                                                                                          |
| <i>Exit Mode</i>                | - exit gearbox immediately<br>- slowdown before exit                                                                                                                                                                                              |
| <i>Coupling Mode</i>            | - with constant acceleration<br>- with constant distance<br>- with constant acceleration and phase correction                                                                                                                                     |

### Slave Phase Shift Adjustment

The slave phase shift allows adjusting the slave's phase to the master's phase: a small displacement can be superimposed on the current slave movement:

- the slave phase shift adjustment can be automatically executed with coupling mode = "constant acceleration with phase correction",
- or the slave phase shift Adjustment can be manually executed.
- the acceleration and deceleration are defined by 0x6083 and 0x6084, the speed is defined by "differential speed" (0x392C).

Gearbox synchronization techniques:

- When “Gearbox Ratio Modulation Source” is defined, the gearbox runs in frequency synchronization.
- Otherwise, the gearbox runs in frequency and phase synchronization. There are two possibilities to define the gearbox ratio:
  - o If both Master Modulo (0x3911,0) and Slave Modulo (0x3927,0) are not at zero, then the gearbox ratio is defined with Slave\_Modulo/Master\_Modulo.
  - o If Master Modulo = 0 or Slave Modulo = 0, then the gearbox ratio is defined with gearbox ratio Num/Den (0x3921).

### Gearbox Function Objects

### Gearbox Ratio Modulation Source

| Index         | 0x3920                        |
|---------------|-------------------------------|
| Name          | Gearbox Ratio Source          |
| Description   | Index/sub-index of input data |
| Data Type     | Unsigned32                    |
| Class         | sq, gb                        |
| Access        | rw                            |
| PDO Mapping   | No                            |
| Value         | See below                     |
| Default Value | 0x00000000                    |

This object allows connecting any 16-bit dataflow as a modulation signal applied to the current ratio set. The modulation value is from 0 to 0x7FFF.

The structure of the entries is the following:

| MSB            | LSB                   |
|----------------|-----------------------|
| Index (16-bit) | Sub-index (8-bit)   0 |

#### Example:

0x3920,0 = 0x30F10200

connects analog input 1 as the ratio modulation signal.

## Gearbox Ratio Parameters

| PDO Mapping | No                              |
| Range       | 1 to 65536                      |

Gearing ratio 2 value = Numerator2 / Denominator2, Gearing ratio range is from 1/256 to 256.

## Gearbox Distances Parameter

This object defines Master Distance, Slave Distance and Synchronization Distance for the gearbox mode. For gearbox sequence in sequence mode, there are 3 equivalence parameters defined in each sequence.

This parameter allows defining the behaviour of the gearbox function for gearbox mode.

In gearbox mode, object 0x3928,1 is taken into account when the gearbox is activated. It cannot be modified when the gearbox is running.

In a gearbox sequence, an equivalence parameter is defined in sequence parameter with a different value for each gearbox sequence.

| Bit Number | Function                                                                                                                                                            |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0..1       | Exit Mode:<br>0 slowdown<br>1 immediate<br>Exit Mode allows exiting immediately the gearbox sequence and link to another sequence without stopping the motor.       |

| Access      | rw                   |
| PDO Mapping | Possible             |

This parameter defines a ratio factor applied to the master-slave ratio,

$$\text{Factor} = \text{Gearbox\_Ratio\_Factor} / 32768$$

If Gearbox\_Ratio\_Factor = 0, no ratio Factor is applied.

In a gearing sequence, an equivalence factor is defined in sequence parameter with a different value for each gearing sequence.

### **3.2.5 - APPLICATION FEATURE**

#### **3.2.5.1 - Digital Input/Output configuration**

##### **Digital Inputs / Outputs**

The ServoPac TT drive allows:

- connecting any physical logic input to any bit in any variable,
- connecting any bit in any variable to any physical logic output.

The available logic input functions are:

- Negative Limit Switch
- Positive Limit Switch
- Homing Switch
- Inhibit

| Index  | Object | Name                          | Type       | Attr. |
|--------|--------|-------------------------------|------------|-------|
| 0x60FD | VAR    | Digital Inputs                | Unsigned32 | ro    |
| 0x3050 | ARRAY  | Digital Inputs Configuration  | Unsigned32 | rw    |
| 0x3051 | VAR    | Digital Inputs Polarity       | Unsigned16 | rw    |
| 0x60FE | ARRAY  | Gem Digital Outputs           | Unsigned32 | rw    |
| 0x3054 | ARRAY  | Digital Outputs Configuration | Unsigned32 | rw    |
| 0x3055 | VAR    | Digital Outputs Polarity      | Unsigned16 | rw    |
| 0x3058 | ARRAY  | Digital User Inputs/Outputs   | Unsigned16 | rw    |
| 0x3059 | ARRAY  | Virtual Inputs/Outputs        | Unsigned16 | rw    |
| 0x3043 | ARRAY  | Enable Configuration          | Unsigned16 | rw    |

Example: realize an ENABLE input with physical input IN1.

- Drive can move only when 24 V supply is applied,
- When 24 V is lost, drive must stop.

So, IN1 input must be connected to the "Inhibit" function with 0x3050. When the "Inhibit" function is activated with logic level 1, the input polarity of IN1 must be reversed by object 0x3051.

## Digital Inputs Configuration

|                    |                              |
|--------------------|------------------------------|
| <b>Index</b>       | <b>0x3050</b>                |
| Name               | Digital Inputs Configuration |
| Object Code        | ARRAY                        |
| Number of Elements | 8                            |

The digital Inputs configuration allows affecting any digital input to one bit in a variable indicated by index and sub-index.

### Value Description

|               |                                                                                                |
|---------------|------------------------------------------------------------------------------------------------|
| Sub Index     | 1-8                                                                                            |
| Description   | Digital Inputs Destination defines the destination object for the corresponding digital input. |
| Data Type     | Unsigned32                                                                                     |
| Access        | rw                                                                                             |
| PDO Mapping   | No                                                                                             |
| Value Range   |                                                                                                |
| Default Value |                                                                                                |

The structure of the entries is the following:

|                |                   |                     |
|----------------|-------------------|---------------------|
| MSB            |                   | LSB                 |
| Index (16-bit) | Sub-index (8-bit) | Bit number n (0-15) |

The state of the physical input will be copied into bit n of the object indicated by index and sub-index.

## Digital Inputs Polarity

| 31  |                        |

|               |                        |
|---------------|------------------------|
| Sub Index     | 2                      |
| Description   | Digital Output Bitmask |
| Data Type     | Unsigned32             |
| Access        | rw                     |
| PDO Mapping   | No                     |
| Default Value | 0                      |

If the Digital Output Bitmask corresponding to "Motor Brake" (bit 0) is set, the sub 1 allows the manual control of the motor brake. Otherwise, the motor brake is automatically controlled when the drive is enabled/disabled with a delay.

## Digital Outputs Configuration

|                    |                               |
|--------------------|-------------------------------|
| <b>Index</b>       | <b>0x3054</b>                 |
| Name               | Digital Outputs Configuration |
| Object Code        | ARRAY                         |
| Number of Elements | 4                             |

The digital outputs configuration allows affecting one bit of any variable indicated by the index and sub-index to a physical output.

### Value Description

|               |                                                              |
|---------------|--------------------------------------------------------------|
| Sub Index     | 1-4                                                          |
| Description   | Digital Output Source defines the source for digital output. |
| Data Type     | Unsigned32                                                   |
| Access        | rw                                                           |
| PDO Mapping   | No                                                           |
| Value Range   |                                                              |
| Default Value |                                                              |

The structure of the entries is the following:

|                |                   |                     |
|----------------|-------------------|---------------------|
| MSB            |                   | LSB                 |
| Index (16-bit) | Sub-index (8-bit) | Bit number n (0-31) |

The state of bit n of the object index and sub-index will be copied to the physical output.

| 15  | Resolver Virtual Top Z (defined by 0x3107) |

## Virtual Inputs/Outputs

|                    |                        |
|--------------------|------------------------|
| <b>Index</b>       | <b>0x3059</b>          |
| Name               | Virtual Inputs/Outputs |
| Object Code        | ARRAY                  |
| Object Class       | all                    |
| Number of Elements | 2                      |

### Value Description

|               |                |
|---------------|----------------|
| Sub Index     | 1              |
| Description   | Virtual Inputs |
| Data Type     | Unsigned16     |
| Access        | rw             |
| PDO Mapping   | Yes            |
| Default Value | No             |

The Pac drive has 5 virtual inputs IN6 to IN10 (bit 5 to bit 9).

These virtual inputs can be connected to drive function with object 0x3050 in the same manner as for a physical input.

|               |                 |
|---------------|-----------------|
| Sub Index     | 2               |
| Description   | Virtual Outputs |
| Data Type     | Unsigned16      |
| Access        | ro              |
| PDO Mapping   | Yes             |
| Default Value | 0               |

The Pac drive has 3 virtual outputs OUT4 to OUT6 (bit 3 to bit 5).

These virtual outputs can be connected to drive signal with object 0x3054 in the same manner as for a physical output.

|               |               |
|---------------|---------------|
| Sub Index     | 3             |
| Description   | Virtual link. |
| Data Type     | Unsigned16    |
| Access        | rw            |
| PDO Mapping   | No            |
| Default Value | 0             |

This parameter allows connecting the virtual outputs to the virtual inputs.

| bit   | Function                                 |
|-------|------------------------------------------|
| 0..2  | reserved                                 |
| 3     | 0 no connection<br>1 connect OUT4 to IN6 |
| 4     | 0 no connection<br>1 connect OUT5 to IN7 |
| 5     | 0 no connection<br>1 connect OUT6 to IN8 |
| 6..15 | reserved                                 |

Example: Make a controlled stop when power supply is down.

- Define the undervoltage warning level (above the under-voltage fault). This is used to notify when power supply is down.
- Connect the undervoltage warning bit to OUT4  
0x3054,4 = 0x30240013
- Connect OUT4 to IN6  
0x3059,3 = 8
- Connect IN6 to INHIBIT signal  
0x3051,6 = 0x60FD0003
- Define an appropriate stop for the INHIBIT signal

### 3.2.5.2 - Analog Inputs/Output

ServoPac TT servo drives have 2 analog inputs:

| Index  | Object | Name           | Type | Attr. |
|--------|--------|----------------|------|-------|
| 0x30F1 | RECORD | Analog Input 1 |      | rw    |
| 0x30F2 | RECORD | Analog Input 2 |      | rw    |

#### Analog Inputs

|                    |                |
|--------------------|----------------|
| Index              | 0x30F1, 0x30F2 |
| Name               | Analog Input   |
| Object Code        | RECORD         |
| Number of Elements | 7              |

#### Value Description

|               |                                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------------------------------|
| Sub Index     | 1                                                                                                                 |
| Description   | Analog Input 16-bit Value<br>Conversion data from ADC. The sampling rate is 16 kHz<br>The result is left aligned. |
| Data Type     | Integer16                                                                                                         |
| Access        | ro                                                                                                                |
| PDO Mapping   | Yes                                                                                                               |
| Value Range   | No                                                                                                                |
| Default Value | No                                                                                                                |

|               |                           |
|---------------|---------------------------|
| Sub Index     | 2                         |
| Description   | Analog Input 32-bit Value |
| Data Type     | Integer32                 |
| Access        | ro                        |
| PDO Mapping   | Yes                       |
| Value Range   | No                        |
| Default Value | No                        |

Analog\_Input\_32bit\_Value = (Analog\_Input\_16bit\_Value - Offset) \* Gain / 256  
The Gain value is signed.

Example: using analog input as speed reference.

The speed reference is 32-bits, so the 32-bit value will be used.

Let's say that the maximum speed is 30000 rpm and the unit is inc/s with 4096 inc per motor revolution.

Maximum speed: 30000 rpm -> 500 rev/s -> 2048000 inc/s

The maximum 16-bit analog input is 32767

Gain = 2048000 / 32767 \* 256 = 16000

|               |           |
|---------------|-----------|
| Sub Index     | 3         |
| Description   | Offset    |
| Data Type     | Integer16 |
| Access        | rw        |
| PDO Mapping   | Yes       |
| Value Range   | -         |
| Default Value | 0         |

|               |           |
|---------------|-----------|
| Sub Index     | 4         |
| Description   | Gain      |
| Data Type     | Integer16 |
| Access        | rw        |
| PDO Mapping   | Yes       |
| Value Range   | -         |
| Default Value | 256       |

|               |            |
|---------------|------------|
| Sub Index     | 5          |
| Description   | Filter     |
| Data Type     | Unsigned16 |
| Access        | rw         |
| PDO Mapping   | Yes        |
| Unit          | Hz         |
| Value Range   | 5-20000    |
| Default Value | 100        |

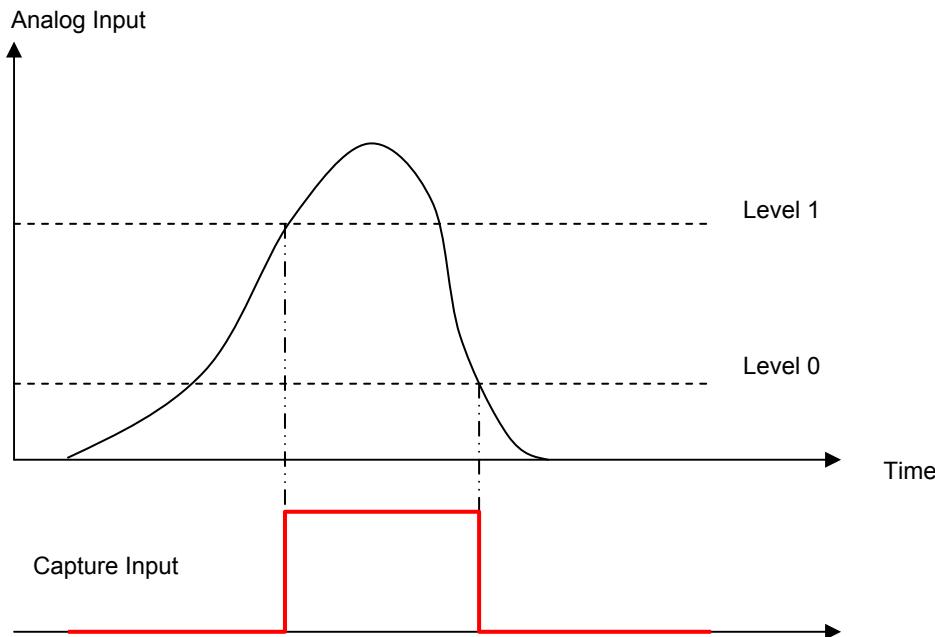

The filter is applied on Analog Input 16-bit Value.

|               |                   |
|---------------|-------------------|
| Sub Index     | 6                 |
| Description   | Analog In Level 0 |
| Data Type     | Integer16         |
| Access        | rw                |
| PDO Mapping   | No                |
| Value Range   |                   |
| Default Value |                   |

This parameter defines level 0 for position capture with analog input (see diagram below).

|               |                   |
|---------------|-------------------|
| Sub Index     | 7                 |
| Description   | Analog In Level 1 |
| Data Type     | Integer16         |
| Access        | rw                |
| PDO Mapping   | No                |
| Value Range   |                   |
| Default Value |                   |

This parameter defines level 1 for position capture with analog input (see diagram below).

The **ServoPac TT** drive has 1 analog output:

- PWM techniques at 48 kHz
- output sampling at 2 kHz
- output signal can be connected to any variable

### Object definitions

| Index  | Object | Name          | Type | Attr. |
|--------|--------|---------------|------|-------|
| 0x30A1 | RECORD | Analog Output |      | rw    |

### Analog Output

| Name               | Analog Output  |
| Object Code        | RECORD         |
| Number of Elements | 4              |

### Value Description

|              |               |
|--------------|---------------|
| Sub Index    | 1             |
| Description  | Analog Output |
| Data Type    | Integer16     |
| Object Class | all           |
| Access       | rw            |
| PDO Mapping  | Yes           |

This object monitors the output value when a source is connected.

Output value is from -32768 to 32767 for 0 V to 5 V on physical analog output.

Output value can be "directly" written (e.g. over Fieldbus) but you have to make sure that there is no source connected ("Index/sub-index of Analog Output source" = 0). The output value is defined by:

$$\text{Physical\_Analog\_Output} = (\text{Analog Output} + \text{Analog\_Output\_Offset}) * \text{Analog\_Output\_Gain} / 256$$

|               |                                         |
|---------------|-----------------------------------------|
| Sub Index     | 2                                       |
| Description   | Index/sub-index of Analog Output source |
| Data Type     | Unsigned32                              |
| Object Class  | all                                     |
| Access        | rw                                      |
| PDO Mapping   | No                                      |
| Value         | See below                               |
| Default value | 0x30F80100<br>0x30F80200                |

This object allows connecting any dataflow as input source of the Analog Output module.

The structure of the entries is the following:

|     |                |                   |     |
|-----|----------------|-------------------|-----|
| MSB | Index (16-bit) | Sub-index (8-bit) | LSB |
|     |                | 0                 |     |

The output value is defined by:

$$\text{Physical\_Analog\_Output} = (\text{Source\_signal} + \text{Analog\_Output\_Offset}) * \text{Analog\_Output\_Gain} / 256$$

|               |                      |
|---------------|----------------------|
| Sub Index     | 3                    |
| Description   | Analog Output Offset |
| Data Type     | Integer16            |
| Object Class  | all                  |
| Access        | rw                   |
| PDO Mapping   | No                   |
| Default Value | 0                    |

|               |                    |
|---------------|--------------------|

| Description   | Analog Output Gain |
| Data Type     | Integer16          |
| Object Class  | all                |
| Access        | rw                 |
| PDO Mapping   | No                 |
| Default Value | 0x0100             |

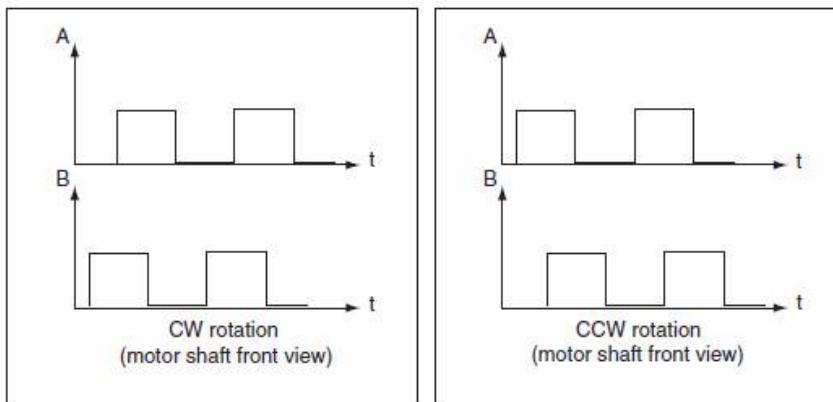

### 3.2.5.3 - Encoder Emulation Output

The **ServoPac** version "TT-CAN" has an encoder emulation output.

"Incremental Encoder" module features:

- emulates an incremental encoder output with the resolver position or the encoder position.
- sends any value from a different of 2 variables to the incremental output
- output signal as quadrature signals or pulse/dir signals

Two A and B channels in quadrature with one Z marker pulse per revolution allow closing the position loop via the DNC.

The **Output encoder resolution** parameter is chosen according to following table:

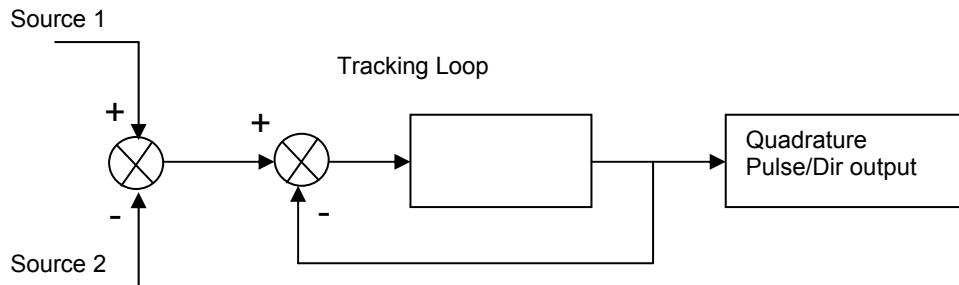

|                                 |              |             |             |             |             |
|---------------------------------|--------------|-------------|-------------|-------------|-------------|
| Maximum motor speed (rpm)       | up to 1600   | up to 3200  | up to 6400  | up to 12800 | up to 25000 |
| Encoder output resolution (ppr) | 512 to 16384 | 512 to 8192 | 512 to 4096 | 512 to 2048 | 512 to 1024 |

## Object definitions

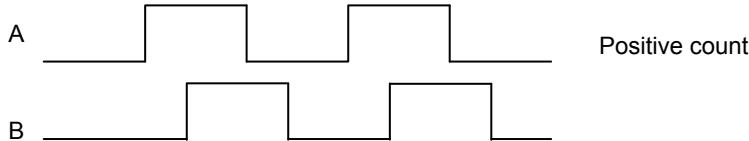

| Index  | Object | Name                       | Type | Attr. |
|--------|--------|----------------------------|------|-------|
| 0x3160 | RECORD | Incremental Encoder Output |      | rw    |

## Encoder Output

Structure of the Encoder output:

## Quadrature output:

The top Z width is 1/4 of signal period.

| Index              | 0x3160         |
|--------------------|----------------|
| Name               | Encoder Output |
| Object Code        | RECORD         |
| Number of Elements | 6              |

## **Value Description**

|               |                                   |
|---------------|-----------------------------------|
| Sub Index     | 1                                 |
| Description   | Index/sub-index of input source 1 |
| Data Type     | Unsigned32                        |
| Object Class  | all                               |
| Access        | rw                                |
| PDO Mapping   | No                                |
| Value         | See below                         |
| Default value | 0x31000400                        |

This object allows connecting any dataflow as input source of the Encoder Output module.

The structure of the entries is the following:

| MSB            | LSB               |
|----------------|-------------------|
| Index (16-bit) | Sub-index (8-bit) |

|               |                                   |
|---------------|-----------------------------------|
| Sub Index     | 2                                 |
| Description   | Index/sub-index of input source 2 |
| Data Type     | Unsigned32                        |
| Object Class  | all                               |
| Access        | rw                                |
| PDO Mapping   | No                                |
| Value         | See above                         |
| Default value | 0                                 |

If value is 0, source 2 is not connected.

|               |                           |

| 12         | 0 Quadrature output<br>1 Pulse/Dir output                                                                                                                                                        |
| 15         | reserved, must be 0                                                                                                                                                                              |

When the "Encoder Emulation" bit is set, a scaling of the input variable (reference by sub-index 1) is the following:

input value from 0 to 0xFFFF is scaled to output value of 0 to (resolution x 4)

Only the lower 16-bit of the input value is processed.

If the "Encoder Emulation" bit is cleared, output value = input value.

Example: Encoder Output Emulation with resolver value.

```
0x3160,6 = 0          ; disables encoder output
0x3160,1 = 0x31000400 ; connects encoder output source to the resolver 16-bit value
0x3160,2 = 0
0x3160,3 = 1024       ; resolution : 1024
0x3160,6 = 0xE03      ; enables encoder output
```

To emulate the encoder output with An Encoder Input, just set 0x3160,1 = 0x31200400.

### 3.2.5.4 - Digital Cam

#### Digital Cam

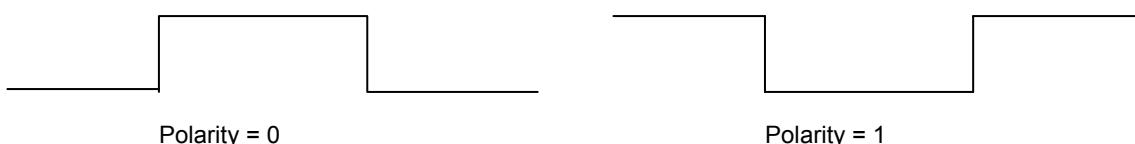

| Index  | Object | Name                               | Type       | Attr. |
|--------|--------|------------------------------------|------------|-------|
| 0x30E0 | ARRAY  | Digital Cam positions              | Integer32  | rw    |
| 0x30E1 | ARRAY  | Digital Cam configuration register | Unsigned16 | rw    |

Cams are fully defined by objects 0x30E0 and 0x30E1. No parameter can be changed if Cam Enable Register is not 0.

#### Cam Polarity

Each bit of the Cam Polarity Register allows setting the polarity of the cam output. Normal polarity (polarity bit = 0) sets the cam output with value 1 when the cam is active.

Cam Output

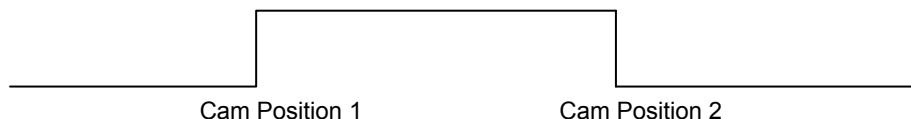

### Cam Type

Each bit of the Cam Type Register defines the cam type.

Cam Type = 0: Cam defined by 1 position.

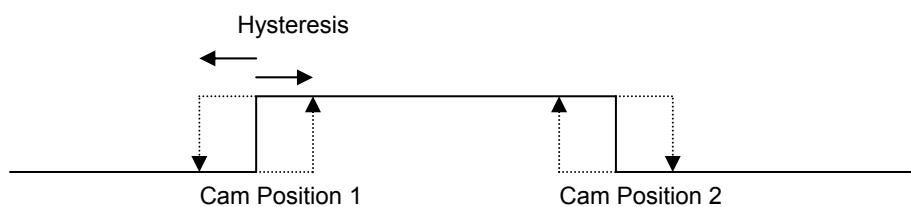

Cam Type = 1: Cam defined by 2 positions.

### Cam Hysteresis

Cam Hysteresis Register defines a hysteresis of the cam position.

### Digital Cam Positions

| Index              | 0x30E0                |
|--------------------|-----------------------|
| Name               | Digital Cam Positions |
| Object Code        | ARRAY                 |
| Number of Elements | 32                    |

Digital Cam Positions can only be changed when Cam Enable Register = 0 (0x30E1-5).

#### Value Description

|               |                                |

| Data Type     | Integer32                      |
| Access        | rw                             |
| PDO Mapping   | Yes                            |
| Value Range   | No                             |
| Default Value | No                             |

|               |                                 |
|---------------|---------------------------------|
| Sub Index     | 2                               |
| Description   | Second Position of Cam number 1 |
| Data Type     | Integer32                       |
| Access        | rw                              |
| PDO Mapping   | Yes                             |
| Value Range   | No                              |
| Default Value | No                              |

## Digital Cam Configuration Registers

|                    |                                     |
|--------------------|-------------------------------------|
| <b>Index</b>       | <b>0x30E1</b>                       |
| Name               | Digital Cam Configuration Registers |
| Object Code        | ARRAY                               |
| Number of Elements | 5                                   |

Registers with sub-indexes 2 to 4 can only be changed when Cam Enable Register = 0.

### Value Description

|               |            |
|---------------|------------|
| Sub Index     | 1          |
| Description   | Cam Status |
| Data Type     | Unsigned16 |
| Access        | ro         |
| PDO Mapping   | Yes        |
| Value Range   | No         |
| Default Value | No         |

Each bit of Cam status register corresponds to a Digital Cam (max. 16 cams)

|               |            |
|---------------|------------|
| Sub Index     | 2          |
| Description   | Cam Type   |

| PDO Mapping   | No           |
| Value Range   | -            |
| Default Value | 0            |

Each bit of Cam Polarity register corresponds to a Digital Cam (max. 16 cams)

- 0 Cam with normal polarity
- 1 Cam with reversed polarity

|               |                |
|---------------|----------------|
| Sub Index     | 4              |
| Description   | Cam Hysteresis |
| Data Type     | Unsigned16     |
| Access        | rw             |
| PDO Mapping   | No             |
| Value Range   | -              |
| Unit          | position unit  |
| Default Value | 0              |

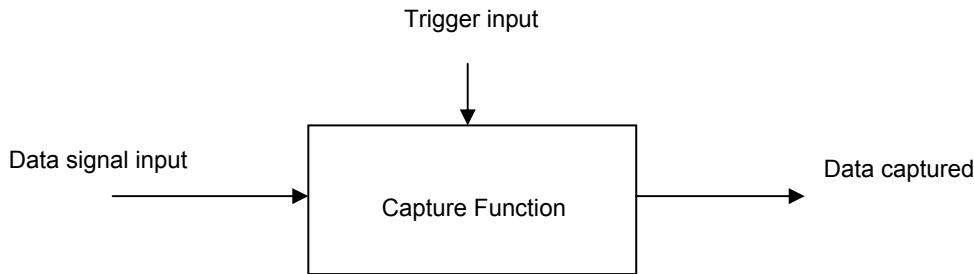

|               |            |
|---------------|------------|
| Sub Index     | 5          |
| Description   | Cam Enable |
| Data Type     | Unsigned16 |
| Access        | rw         |
| PDO Mapping   | No         |
| Value Range   | -          |
| Default Value | 0          |

Each bit of Cam Enable register corresponds to a Digital Cam (max. 16 cams)

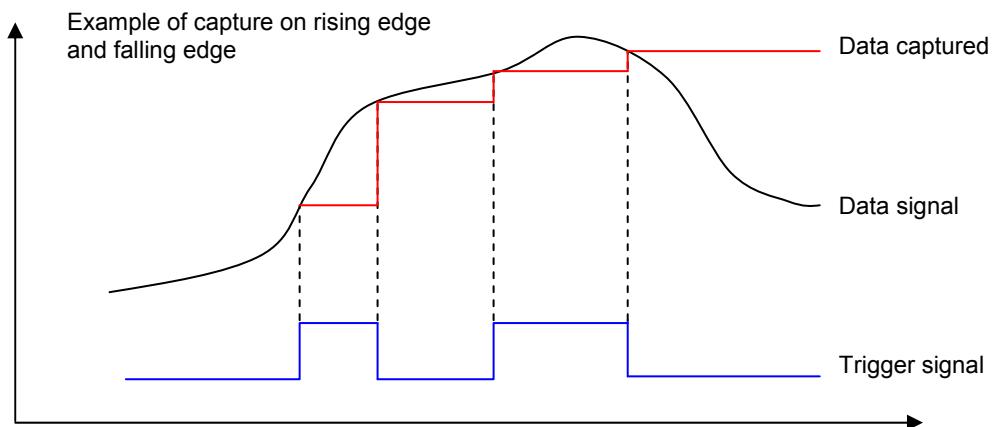

- 0 Disable Cam
- 1 Enable Cam

### **3.2.5.5 - Capture**

#### **Capture/Touch probe Function**

The purpose of the capture function is to latch a data signal (generally position value from a sensor) on a trigger input signal (generally a logic input).

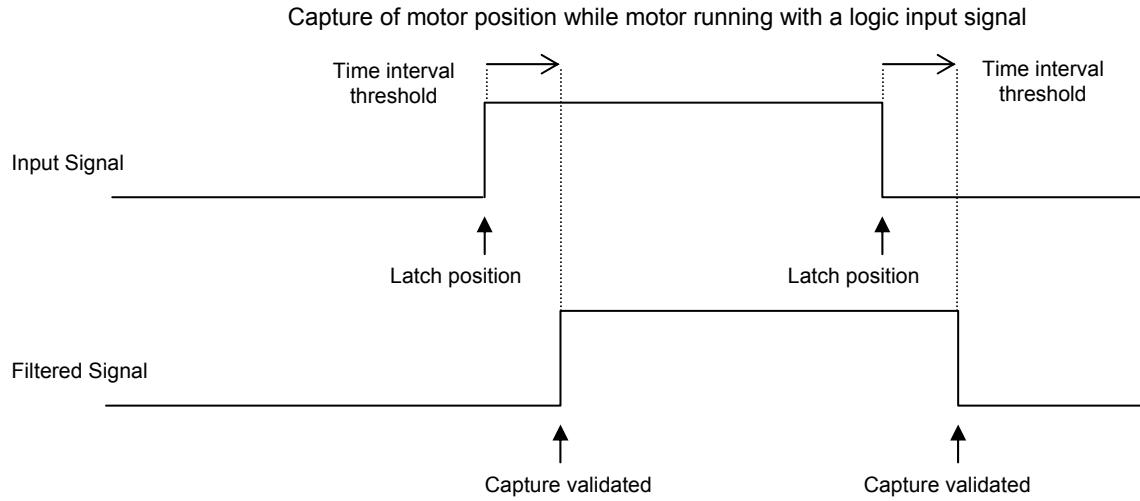

#### **ServoPac TT capture features:**

- The data signal can be a resolver position value or an encoder position value,
- The trigger input signal can be any of the physical logic inputs, any of the analog inputs or the encoder marker Z,
- The capture can be triggered on rising edge, falling edge or both.
- The trigger input signal can be filtered by a time filter,
- The data signal can be filtered by a space filter.

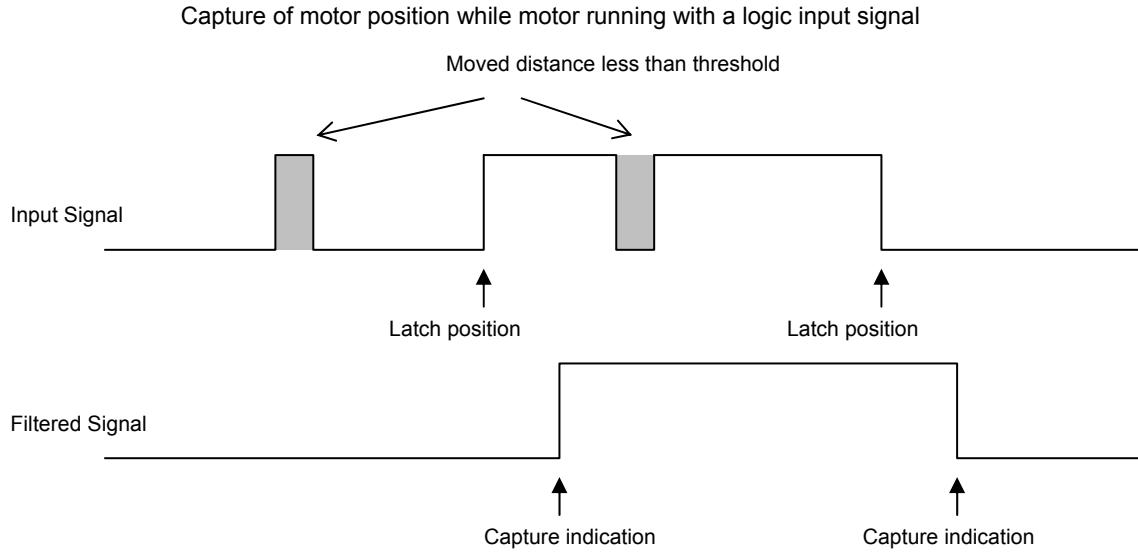

### Capture Time Filter

This parameter defines the time interval threshold of the capture time filter. After the rising or falling edge of the input signal, the input signal level must be stable for a time interval value greater than or equal to the time interval threshold defined by object 0x3371-4 (0x3372-4) in order to get the position capture validated as described below.

### Capture Space Filter

This parameter defines the value in distance threshold of the capture position filter. If the position gap between rising and falling edges is less than the threshold, then the signal is the following:

## Objects definition

| Index  | Object | Name                    | Type       | Attr. |
|--------|--------|-------------------------|------------|-------|
| 0x3370 | VAR    | Capture Status          | Unsigned16 | ro    |
| 0x337F | VAR    | Capture Status for TPDO | Unsigned16 | ro    |
| 0x3371 | RECORD | Capture 1               |            | rw    |
| 0x3372 | RECORD | Capture 2               |            | rw    |
| 0x3373 | RECORD | Capture 3               |            | rw    |
| 0x3374 | RECORD | Capture 4               |            | rw    |

The capture 1 and capture 2 can be accessed by CANopen DSP-402 interface (Touch Probe):

| Index  | Object | Name                            | Type       | Attr. |
|--------|--------|---------------------------------|------------|-------|
| 0x60B8 | VAR    | Touch Probe Function            | Unsigned16 | rw    |
| 0x60B9 | VAR    | Touch Probe Status              | Unsigned16 | ro    |
| 0x60BA | VAR    | Touch Probe Pos1 Positive Value | Integer32  | ro    |
| 0x60BB | VAR    | Touch Probe Pos1 Negative Value | Integer32  | ro    |
| 0x60BC | VAR    | Touch Probe Pos2 Positive Value | Integer32  | ro    |
| 0x60BD | VAR    | Touch Probe Pos2 Negative Value | Integer32  | ro    |
| 0x60D0 | ARRAY  | Touch Probe Source              |            | rw    |

## Capture objects

### Capture Status

| Index         | 0x3370         |
|---------------|----------------|
| Description   | Capture Status |
| Data Type     | Unsigned16     |
| Access        | ro             |
| PDO Mapping   | Possible       |
| Value         | -              |
| Default value | -              |

| Bit Number | Function                                                    |
|------------|-------------------------------------------------------------|
| 0          | Capture 1 enabled                                           |
| 1          | Capture Input 1 image                                       |
| 2          | Change state: a capture on rising edge of input 1 occurred  |
| 3          | Change state: a capture on falling edge of input 1 occurred |
| 4          | Capture 2 enabled                                           |
| 5          | Capture Input 2 image                                       |
| 6          | Change state: a capture on rising edge of input 2 occurred  |
| 7          | Change state: a capture on falling edge of input 2 occurred |
| 8          | Capture 3 enabled                                           |
| 9          | Capture Input 3 image                                       |
| 10         | Change state: a capture on rising edge of input 3 occurred  |
| 11         | Change state: a capture on falling edge of input 3 occurred |
| 12         | Capture 4 enabled                                           |
| 13         | Capture Input 4 image                                       |
| 14         | Change state: a capture on rising edge of input 4 occurred  |
| 15         | Change state: a capture on falling edge of input 4 occurred |

The Capture Status is clear when writing to Capture configuration (0x337n-1)

## Capture Status for PDO

|               |                        |
|---------------|------------------------|
| <b>Index</b>  | <b>0x337F</b>          |
| Description   | Capture Status for PDO |
| Data Type     | Unsigned16             |
| Access        | ro                     |

| 13                | Capture Input 4 image                         |
| 14                | A capture on rising edge of input 2 occurred  |
| 15                | A capture on falling edge of input 2 occurred |

Capture indicators (bit 2, 3, 6, 7, 10, 11, 14, 15) are cleared when this object is sent by a PDO.

## Capture Parameters

|                    |                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------|
| <b>Index</b>       | 0x3371 for capture 1<br>0x3372 for capture 2<br>0x3373 for capture 3<br>0x3374 for capture 4 |
| Name               | Capture Parameters                                                                           |
| Object Code        | RECORD                                                                                       |
| Number of Elements | 8                                                                                            |

## Value Description

|                  |                        |
|------------------|------------------------|
| <b>Sub Index</b> | 1                      |
| Description      | Capture 1/2/3/4 Config |
| Data Type        | Unsigned16             |
| Access           | rw                     |
| PDO Mapping      | No                     |

| <b>Bit Number</b> | <b>Function</b>         |
|-------------------|-------------------------|
| 0                 | Capture on rising edge  |
| 1                 | Capture on falling edge |
| 15                | Enable Capture          |

|             |                        |
|-------------|------------------------|
| Sub Index   | 2                      |
| Description | Capture 1/2/3/4 source |
| Data Type   | Unsigned32             |
| Access      | rw                     |
| PDO Mapping | No                     |

This parameter allows connecting a 32-bit dataflow as input of the capture data signal.

Only objects 0x3109 (resolver position) and 0x3129 (encoder position) are supported.

The structure of the entries is the following:

| MSB            | LSB               |
|----------------|-------------------|
| Index (16-bit) | Sub-index (8-bit) |

Example:

Capture 1 data is connected to resolver position:  
0x3371,2 = 0x31090000

|             |                       |
|-------------|-----------------------|
| Sub Index   | 3                     |
| Description | Capture 1/2/3/4 Input |
| Data Type   | Unsigned16            |
| Access      | rw                    |
| PDO Mapping | No                    |

This parameter allows defining a logic input as capture trigger signal.

| Value | Function      |
|-------|---------------|
| 0     | IN1           |
| 1     | IN2           |
| 2     | IN3           |
| 3     | IN4           |
| 4     | IN5           |
| 5     |               |
| 6     |               |
| 7     |               |
| 8     |               |
| 9     |               |
| 10    |               |
| 11    |               |
| 12    | Analog In 1   |
| 13    | Analog In 2   |
| 14    | Encoder Top Z |
| 15    | Resolver 0    |

IN1 .. IN5 are physical inputs.

The capture triggered by the analog input is defined by analog levels (0x30F1).

| PDO Mapping      | No                   |
| Value            | See table above      |
| Default Value    | -5                   |

### 3.2.5.6 - Modulo function

|               |                      |
|---------------|----------------------|
| <b>Index</b>  | <b>0x307B</b>        |
| Name          | Modulo configuration |
| Object Code   | VAR                  |
| Data Type     | Unsigned16           |
| Object Class  | all                  |
| Access        | rw                   |
| PDO Mapping   | No                   |
| Default Value | 0                    |

The motor position can be limited by the position limit function (modulo function).

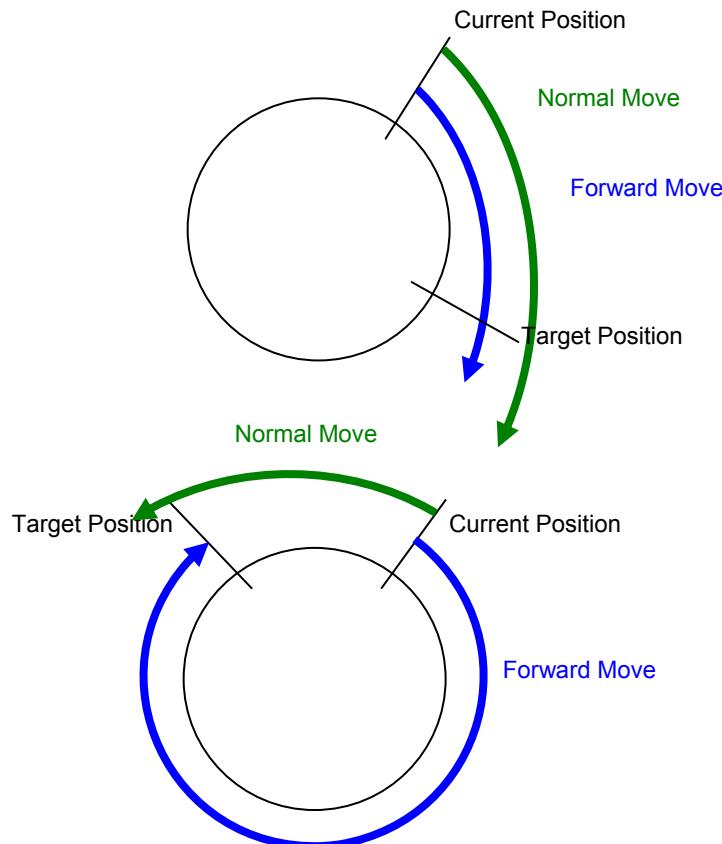

Minimum Position Limit <= Motor Position < Maximum Position Limit

| Bit Number | Function                                      |
|------------|-----------------------------------------------|
| 0          | Modulo Function<br>0 disable<br>1 enable      |
| 2          | Forward (always in positive direction)        |
| 3          | Backward (always in negative direction)       |
| 4          | CLEAR input function<br>0 disable<br>1 enable |

- "Forward" and "Backward" cannot be set at the same time.
- "Modulo Enable/Disable" (bit 0) and CLEAR input function (bit 4) cannot be changed when drive is enabled.

#### Modulo Function with forward:

The forward bit forces the motor to move always in positive direction.

#### CLEAR input function:

The CLEAR input function allows using the HOME input (0x60FD) to reset the position value.

CLEAR input function and modulo function must not be activated at the same time.

The motor position can be limited by the position limit function or modulo function.

The modulo function is enabled / disabled by object 0x307B.

Minimum Position Limit <= Motor Position < Maximum Position Limit

The Position Limit values are defined by object 0x607B. These position values can only be changed when the modulo function is disabled.

### 3.2.5.7 - Digital Input/Output extension

#### CANopen I/O extension

The TT-CAN servo drive version can support and manage an external CANopen I/O module in order to get more inputs and outputs.

##### Features:

- Each TT-CAN servo drive can handle one and only one CANopen I/O module DS-401 with or without CANopen master.
- Each I/O module can have up to (extra I/Os are ignored):
  - 16 digital inputs
  - 16 digital outputs
  - 1 analog input
  - 1 analog output
- Communication with I/O can be:
  - SDO only (about 10 ms)
  - PDO only (down to 2 ms)
  - SDO (pre-op) and PDO (operational)
- Assignment:
  - Digital inputs are divided in 2 blocks which can be assigned to any drive variable.
  - Digital outputs are divided in 2 blocks which can be assigned from any drive variable.
  - Analog input can be assigned to any drive variable.
  - Analog Output can be assigned from any drive variable.

**Structure with master****Structure without master**

Sync message is produced by one TT-CAN drive.

**Objects definition**

| Index  | Object | Name                       | Type | Attr. |
|--------|--------|----------------------------|------|-------|
| 0x3821 | RECORD | Digital Inputs Assignment  |      | rw    |
| 0x3822 | RECORD | Digital Outputs Assignment |      | rw    |
| 0x3823 | RECORD | Analog Input Assignment    |      | rw    |
| 0x3824 | RECORD | Analog Output Assignment   |      | rw    |
| 0x3825 | RECORD | Communication Parameters   |      | rw    |
| 0x3828 | RECORD | Control Parameters         |      | rw    |
| 0x3829 | RECORD | Inputs/Outputs values      |      | rw    |

**Digital Inputs Assignment**

|                    |                           |
|--------------------|---------------------------|
| Index              | 0x3821                    |
| Name               | Digital Inputs Assignment |
| Object Code        | RECORD                    |
| Number of Elements | 6                         |

**Value Description**

Two groups of digital inputs can be assigned to 2 drive variables.

variable1 = (digital\_inputs & mask1) shift n1  
 variable2 = (digital\_inputs & mask2) shift n2

|               |                 |
|---------------|-----------------|
| Sub Index     | 1               |
| Description   | Target Object 1 |
| Data Type     | Unsigned32      |
| Access        | rw              |
| PDO Mapping   | No              |
| Default Value | 0               |

This parameter allows connecting digital inputs to a drive variable.

The structure of the entries is the following:

| MSB            | LSB                           |
|----------------|-------------------------------|
| Index (16-bit) | Sub-index (8-bit) size (bits) |

|               |            |
|---------------|------------|
| Sub Index     | 2          |
| Description   | Mask 1     |
| Data Type     | Unsigned16 |
| Access        | rw         |
| Save          | Yes        |
| PDO Mapping   | No         |
| Default Value | 0          |

|               |           |
|---------------|-----------|
| Sub Index     | 3         |
| Description   | Shift 1   |
| Data Type     | integer16 |
| Access        | rw        |
| Save          | Yes       |
| PDO Mapping   | No        |
| Default Value | 0         |

|               |                 |
|---------------|-----------------|
| Sub Index     | 4               |
| Description   | Target Object 2 |
| Data Type     | Unsigned32      |
| Access        | rw              |
| Save          | Yes             |
| PDO Mapping   | No              |
| Default Value | 0               |

This parameter allows connecting digital inputs to a drive variable.

The structure of the entries is the following:

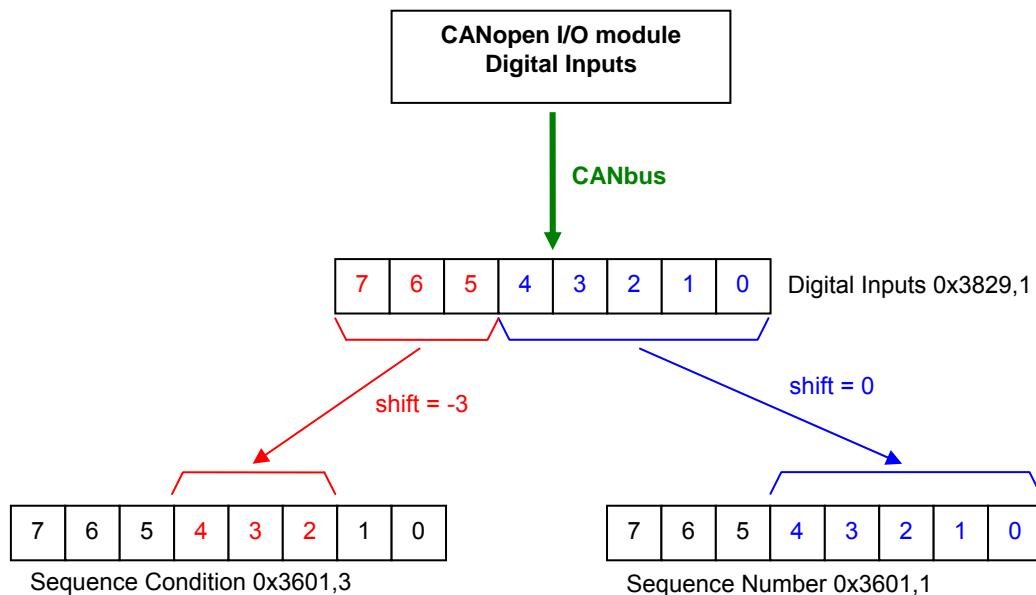

| MSB            | LSB                           |
|----------------|-------------------------------|
| Index (16-bit) | Sub-index (8-bit) size (bits) |

|               |            |
|---------------|------------|
| Sub Index     | 5          |
| Description   | Mask 2     |
| Data Type     | Unsigned16 |
| Access        | rw         |
| Save          | Yes        |
| PDO Mapping   | No         |
| Default Value | 0          |

|               |           |
|---------------|-----------|
| Sub Index     | 6         |
| Description   | Shift 2   |
| Data Type     | integer16 |
| Access        | rw        |
| Save          | Yes       |
| PDO Mapping   | No        |
| Default Value | 0         |

**Example:**

Using I/O Module with 8 inputs: 5 inputs will be used to select sequence number and 3 inputs will be used for sequence condition.

The assignment will be:

The target object is sequence number input: 0x3601,1

The first group of 5 bits are digital inputs (0, 1, 2, 3, 4), so the bit mask is 0x001F

There is no shift between the digital inputs and the target object bits, so the shift value is 0:

`0x3821,1 = 0x36010100`

`0x3821,2 = 0x001F`

`0x3821,3 = 0`

The target object is sequence condition input: 0x3601,3.

The second group of 3 bits are digital input bits (5, 6, 7), so the bit mask is 0x00E0.

The digital input bits start from bit 5 and the target bits start from bit 2, so the shift value is -3

`0x3821,4 = 0x36010300`

`0x3821,5 = 0x00E0`

`0x3821,6 = -3`

Remark: One input can be connected to 2 different target objects.

## Digital Outputs Assignment

|                    |                            |
|--------------------|----------------------------|
| <b>Index</b>       | <b>0x3822</b>              |
| Name               | Digital Outputs Assignment |
| Object Code        | RECORD                     |
| Number of Elements | 6                          |

### Value Description

The digital outputs can come from 2 drive variables:

digital\_outputs = ((variable1 shift n1) and mask1) or ((variable2 shift n2) and mask2)

|               |                 |
|---------------|-----------------|
| Sub Index     | 1               |
| Description   | Source Object 1 |
| Data Type     | Unsigned32      |
| Access        | rw              |
| Save          | Yes             |
| PDO Mapping   | No              |
| Default Value | 0               |

This parameter allows connecting a drive's variable to digital outputs.

The structure of the entries is the following:

| MSB            | LSB               |
|----------------|-------------------|
| Index (16-bit) | Sub-index (8-bit) |
|                | size (bits)       |
|                |                   |
| Sub Index      | 2                 |
| Description    | Mask 1            |
| Data Type      | Unsigned16        |
| Access         | rw                |
| Save           | Yes               |
| PDO Mapping    | No                |
| Default Value  | 0                 |
|                |                   |
| Sub Index      | 3                 |
| Description    | Shift 1           |
| Data Type      | integer16         |
| Access         | rw                |
| Save           | Yes               |
| PDO Mapping    | No                |
| Default Value  | 0                 |
|                |                   |
| Sub Index      | 4                 |
| Description    | Source Object 2   |
| Data Type      | Unsigned32        |
| Access         | rw                |
| Save           | Yes               |
| PDO Mapping    | No                |
| Default Value  | 0                 |

This parameter allows connecting a drive's variable to digital outputs.

The structure of the entries is the following:

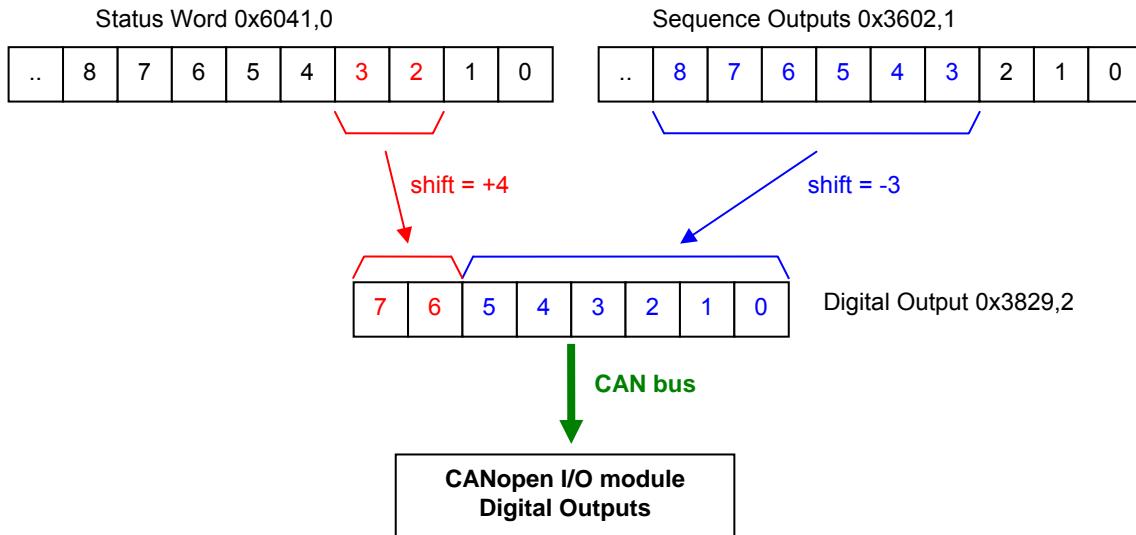

| MSB            | LSB               |
|----------------|-------------------|
| Index (16-bit) | Sub-index (8-bit) |
|                | size (bits)       |

|               |            |
|---------------|------------|
| Sub Index     | 5          |
| Description   | Mask 2     |
| Data Type     | Unsigned16 |
| Access        | rw         |
| Save          | Yes        |
| PDO Mapping   | No         |
| Default Value | 0          |

|               |           |
|---------------|-----------|
| Sub Index     | 6         |
| Description   | Shift 2   |
| Data Type     | integer16 |
| Access        | rw        |
| Save          | Yes       |
| PDO Mapping   | No        |
| Default Value | 0         |

**Example:**

Using I/O Module with 8 outputs: 2 outputs are from status\_word and 6 outputs are from sequence\_outputs

The assignment will be:

The source object is sequence number input: 0x6041,0

The first group of 2 bits are from (2, 3) to output bits (6, 7), so the shift value is +4

The mask for the output bits (6, 7) is 0xC0

0x3822,1 = 0x60410000

0x3822,2 = 0x00C0

0x3822,3 = 4

The source object is sequence outputs: 0x3602,1

The second group of 6 bits are from (3, 4, 5, 6, 7, 8) to outputs bits (0, 1, 2, 3, 4, 5), so the shift value is -3

The mask for the output bits (0, 1, 2, 3, 4, 5) is 0x3F

0x3822,4 = 0x36020100

0x3822,5 = 0x003F

0x3822,6 = -3

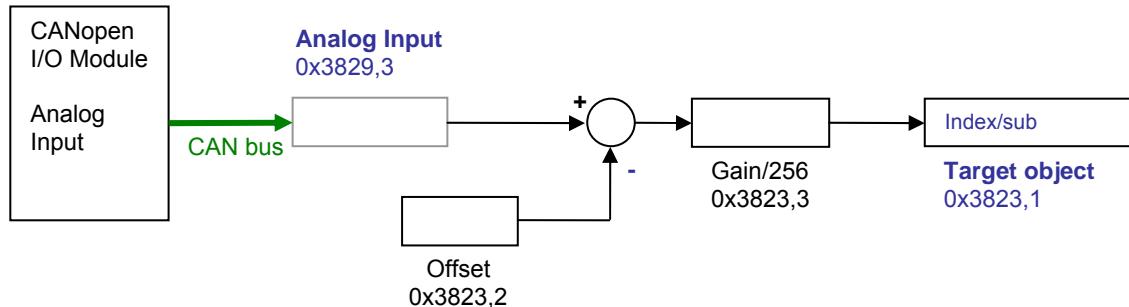

Remark: if 2 source objects are connected to the same output, the output will take the value from the 2nd object.

## Analog Inputs Assignment

|                    |                          |
|--------------------|--------------------------|
| <b>Index</b>       | <b>0x3823</b>            |
| Name               | Analog Inputs Assignment |
| Object Code        | RECORD                   |
| Number of Elements | 3                        |

### Value Description

Analog input can be assigned to a drive's variable:  
variable = (analog\_input - offset) x gain / 256

|                  |                 |
|------------------|-----------------|
| <b>Sub Index</b> | <b>1</b>        |
| Description      | Target Variable |
| Data Type        | Unsigned32      |
| Access           | rw              |
| Save             | Yes             |
| PDO Mapping      | No              |
| Default Value    | 0               |

This parameter allows connecting the analog input to a drive's variable.

The structure of the entries is the following:

| MSB            | LSB                           |
|----------------|-------------------------------|
| Index (16-bit) | Sub-index (8-bit) size (bits) |

|                  |           |
|------------------|-----------|
| <b>Sub Index</b> | <b>2</b>  |
| Description      | Offset    |
| Data Type        | integer16 |
| Access           | rw        |
| Save             | Yes       |
| PDO Mapping      | No        |
| Default Value    | 0         |

|                  |           |
|------------------|-----------|
| <b>Sub Index</b> | <b>3</b>  |
| Description      | Gain      |
| Data Type        | integer16 |
| Access           | rw        |
| Save             | Yes       |
| PDO Mapping      | No        |
| Default Value    | 256       |

**Example:**

Using a 16-bit Analog Input as speed reference (profile velocity mode).

resolution = 4096 inc/rev

max. speed = 3000 rpm

analog input (-32768 .. +32767)

$$\text{max\_speed} = 3000 / 60 \times 4096 = 204800 \text{ inc/s}$$

$$\text{max\_speed} = 32767 \times \text{gain} / 256$$

$$\text{so, gain} = 1600$$

Parameter setting:

0x3823,1 = 0x60FF0000

0x3823,2 = 0

0x3823,3 = 1600

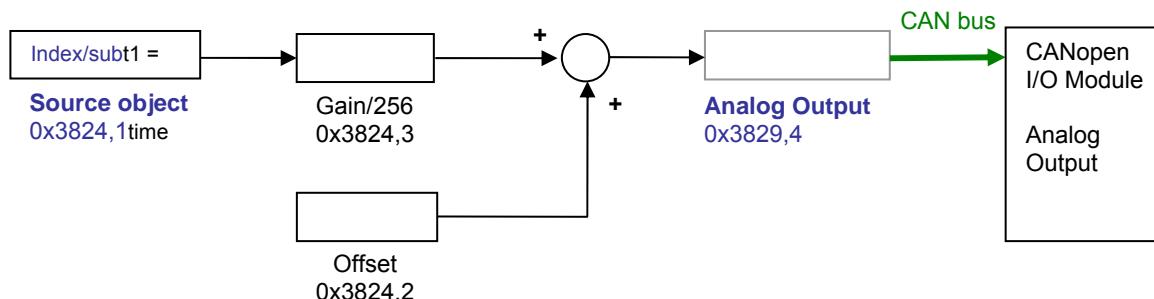

## Analog Outputs Assignment

|                    |                           |
|--------------------|---------------------------|
| <b>Index</b>       | <b>0x3824</b>             |
| Name               | Analog Outputs Assignment |
| Object Code        | RECORD                    |
| Number of Elements | 3                         |

### Value Description

Analog input can be assigned to a drive's variable:

$$\text{analog\_output} = \text{variable} \times \text{gain} / 256 + \text{offset}$$

|                  |                 |
|------------------|-----------------|
| <b>Sub Index</b> | <b>1</b>        |
| Description      | Source Variable |
| Data Type        | Unsigned32      |
| Access           | rw              |
| Save             | Yes             |
| PDO Mapping      | No              |
| Default Value    | 0               |

This parameter allows connecting a drive's variable to the analog output.

The structure of the entries is the following:

| MSB            | LSB                           |
|----------------|-------------------------------|
| Index (16-bit) | Sub-index (8-bit) size (bits) |

|                  |           |
|------------------|-----------|
| <b>Sub Index</b> | <b>2</b>  |
| Description      | Offset    |
| Data Type        | integer16 |
| Access           | rw        |
| Save             | Yes       |
| PDO Mapping      | No        |
| Default Value    | 0         |

|               |           |
|---------------|-----------|
| Sub Index     | 3         |
| Description   | Gain      |
| Data Type     | integer16 |
| Access        | rw        |
| Save          | Yes       |
| PDO Mapping   | No        |
| Default Value | 256       |

### Communication parameters for CANopen I/O module

|                    |                                                 |

|-------------|------------|
| Sub Index   | 2          |
| Description | Control    |
| Data Type   | Unsigned16 |
| Access      | rw         |
| Save        | yes        |
| PDO Mapping | No         |

This parameter defines the I/O module management.

| Bit Number | Function                                          |
|------------|---------------------------------------------------|
| 0          | ↑ Enable I/O module<br>0 Disable I/O module       |
| 1          | Auto-restart after communication lost             |
| 2          | Error if communication lost or module not found   |
| 3, 4       | Reserved. Must be reset at 0                      |
| 5          | Map drive PDO for digital I/O                     |
| 6          | SYNC producer                                     |
| 7          | 1 CAN bus: to operational<br>0 CAN bus: to Pre-op |
| 8          | Digital Input by SDO                              |
| 9          | Digital Output by SDO                             |
| 10         | Analog Input by SDO                               |
| 11         | Analog Output by SDO                              |
| 12         | Digital Input by PDO                              |
| 13         | Digital Output by PDO                             |
| 14         | Analog Input by PDO                               |
| 15         | Analog Output by PDO                              |

Bits 5, 6, 8..15 are taken into account only with rising edge/falling edge of bit 0.

| Description | Analog Outputs<br>this variable is sent to CANopen I/O module analog outputs by SDO/PDO |
| Data Type   | Integer16                                                                               |
| Access      | rw                                                                                      |
| PDO Mapping | Yes                                                                                     |

## 3.2.6 - MAINTENANCE

### 3.2.6.1 - Files

#### ServoPac TT Files

The **ServoPac TT** drive can store data files in its internal Flash memory:

| Name         | Format                | Description                                                                                                                                                                                            |
|--------------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DRIVEPAR.TXT | text<br>object file   | Drive parameters are saved in these files.<br>The user can save drive parameters by means of the Gem Drive Studio software or via the communication bus by means of object 0x1010 (CAN bus, RS-232...) |
| USER_PAR.TXT | text<br>object file   | This file can keep extra parameters by the user.<br>The parameters are set manually and the USER_PAR.TXT file must be sent to the <b>ServoPac TT</b> drive.                                            |
| SEQUENCE.TXT | text<br>sequence file | Sequence files for Positioner Mode                                                                                                                                                                     |

## Object File

### Object file format

The object file (i.e. CANopen object) is a plain text file allowing the definition of an object list in the drive, which values must be defined.

The syntax is:

`index, sub=object_value`

All digital values can be in hexa (preceded by 0x) or decimal.

Only one allocation per line is allowed.

A comment line begins with a ;

All lines that do not begin with a figure will be ignored.

Example:

`0x3549,10=0x12`

means the allocation of value 0x12 to object index 0x3549 sub-index 10

`13641,0xA=18`

gives the same result.

### Notes

- The drive parameter file (DRIVEPAR.TXT) has also got this format.

- The USER\_PAR.TXT file is not mandatory. It allows, for example, defining an initial configuration of the drive directly by the user.

## 3.2.6.2 - Firmware update

### Update File

An Update File contains a file header and one or several data blocks.

```
File_Header
Binary_Block_1
Binary_Block_2
...
Binary_Block_n
```

**File\_Header (32 bytes):**

```
00000000 File_code 'IDUF' (0x46554449)
00000004 File_crc32: from byte 4 to the end of file
00000008 Protect Data length (bytes): file_length - 8
0000000C Device Sectors
00000010 Update_Code
00000012 Number of Binary Blocks
00000014 Number of Block Type
00000016 Version
00000018 Device Address
0000001C reserved
00000020 First Binary Block
```

**Binary\_Block\_k: Block\_Header + Block\_Data**

**Block header (16 bytes):**

```
00000000 Block_crc32: from byte 4 to the end of block
00000004 Block_type: 1-algo, 2-security, 3-code
00000006 Block_Cmd
00000008 Block_addr: Device memory address
0000000C Block_length: length of block data (bytes)
00000010 Block data...
```

## Update Interface

| Value       | transfer data to/from buffer:<br>binary_block (block_header + block_data) |

### Programming sequence

#### Initialization:

|                         |       |                        |
|-------------------------|-------|------------------------|
| Update Code:            | write | 0x5F30,1 = update_code |
| Change to program mode: | write | 0x5F30,2 = 1           |
| Verify program mode:    | read  | 0x5F30,2 = 1           |

#### Erase:

|                       |       |                         |
|-----------------------|-------|-------------------------|
| Number of Blocks:     | write | 0x5F31,1 = n_blocks     |
| Number of Block_type: | write | 0x5F31,2 = n_types      |
| Sectors Mask:         | write | 0x5F31,3 = sectors_mask |
| Erase command:        | write | 0x5F31,4 = 1            |
| Verify erase command: | read  | 0x5F31,4 = 0            |

#### Programming: repeat (n blocks)

|                              |           |                       |
|------------------------------|-----------|-----------------------|
| Write Block_type:            | write     | 0x5F32,1 = block_type |
| Write Block (header & data): | write seg | 0x5F32,5              |
| Program Block command:       | write     | 0x5F32,6 = 1          |
| Verify program command:      | read      | 0x5F32,6 = 0          |

### 3.3 - OBJECT LIST

Parameters in bold are saved into the parameter file.

| Index | Sub | Name | Description |
|-------|-----|------|-------------|
|-------|-----|------|-------------|

#### Communication

|               |  |               |                               |
|---------------|--|---------------|-------------------------------|
| 0x1005        |  | Sync_ID       | Sync CobID                    |
| <b>0x1006</b> |  | <b>Period</b> | Communication Cycle Period    |
| 0x100C        |  | Guard_T       | NodeGuarding Guard Time       |
